## **ANNEXES TO THE NATIONAL INVENTORY REPORT**

### **ANNEX 1: KEY CATEGORIES**

### **1.1. DESCRIPTION OF METHODOLOGY USED FOR IDENTIFYING KEY CATEGORIES, IF DIFFERENT FROM THE INTERGOVERNMENTAL PANEL ON CLIMATE CHANGE (IPCC) TIER 1 APPROACH**

Key categories according to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories (IPCC, 2006) are those found in the accumulative 95% (Tier 1) or 90% (Tier 2) of the total annual emissions in the last reported year or belonging to the total trend, when ranked from contributing the largest to smallest share in annual total and in the trend. As originally designed it applied only to source categories.

Following the 2006 IPCC Guidelines, Croatia undertook a key category analysis using Tier 1 and Tier 2 Level and Trend methods.

#### **Level assessment**

Level assessment involves an identification of categories as a key by calculating the proportion of emissions and removals in each category to the total emissions and removals. The calculated values of proportion are added from the category that accounts for the largest proportion, until the sum reaches 95% for Tier 1, 90% for Tier 2. Tier 1 level assessment uses emissions and removals from each category directly and Tier 2 level assessment analyses the emissions and removals of each category, multiplied by the uncertainty (which is calculated in uncertainty analysis chapter) of each category.

#### **Trend Assessment**

The purpose of the trend assessment is to identify categories that may not be large enough to be identified by the level assessment, but whose trend is significantly different from the trend of the overall inventory and should therefore receive particular attention.

The difference between the rate of change in emissions and removals in a category and the rate of change in total emissions and removals is calculated. The trend assessment is calculated by multiplying this value by the ratio of contribution of the relevant category to total emissions and removals. The calculated results, regarded as trend assessment values, are added from the category of which the proportion to the total of trend assessment values is the largest, until the total reaches 95%

for Tier 1, 90% for Tier 2. At this point, these categories are defined as the key categories. Tier 2 trend assessment is calculated multiplying the Tier 1 trend assessment with uncertainty of each category.

## 1.2. INFORMATION ON THE LEVEL OF DISAGGREGATION

The level of disaggregation is in accordance with the suggested source categories split of the 2006 IPCC Guidelines and Uncertainty Management in National Greenhouse Gas Inventories and additionally.

Approach 1 and Approach 2 have been done in defining and calculating key categories.

## **ANNEX 2: ASSESSMENT OF UNCERTAINTY**

## **ANNEX 2: ASSESSMENT OF UNCERTAINTY**

### **2.1. DESCRIPTION OF METHODOLOGY USED FOR IDENTIFYING UNCERTAINTIES**

Uncertainty estimates are calculated using Approach 2 (Monte Carlo simulation). Approach 2 follows definition from the IPCC's General Guidance and Reporting: 2006 IPCC Guidelines for National Greenhouse gas Inventories (2006 Guidelines).

The Monte Carlo method was reviewed and revised in this submission, taking into account guidance from the 2006 Good Practice Guidance (IPCC, 2006). It will be discussed later in the chapter.

Uncertainty analysis using Approach 2 was calculated for every source. For LULUCF categories and subcategories the analysis was performed in the way of uncertainty determination of all input data and variables; which implies the determination of appropriate distribution for every input parameter needed for calculation of emission factors (EF) and for activity data (AD, areas). For categories of other sectors PDFs were defined for ADs and EFs, respectively. Monte Carlo simulation was applied afterwards. Results can be found in Table 3.3 according to IPCC 2006 Guidelines.

Uncertainty estimates were calculated in Excel spreadsheet application. Data have been divided into five sectors according to modus how the inventory work is organized (Energy, Industrial Processes and Other Product Use, Agriculture, Land Use, Land-Use Change and Forestry and Waste).

Every sector has been divided into sources. Each source was evaluated regarding uncertainties (%) on activity data (AD), emission factors (EF) or direct emissions (EM).

#### **2.1.1 Estimation of Uncertainty by Monte Carlo Simulation (Approach 2)**

##### **Overview of the method**

The Monte Carlo analysis is suitable for detailed category-by-category assessment of uncertainty, particularly where uncertainties are large, distribution is non-normal, distribution functions are complex and/or there are correlations between some of the activity sets, emissions factors, or both.

The principle of Monte Carlo analysis is to select random values of emission factor, activity data and other estimation parameters from within their individual probability density functions, and to calculate the corresponding emission values.

This procedure is repeated many times, using a computer, and the results of each calculation run build up the overall emission probability density function.

Monte Carlo analysis can be performed at the category level, for aggregations of categories or for the inventory as a whole.

Detailed procedure:

- A probability distribution function (PDF) was allocated to each emission factor and activity data. The PDFs were mostly normal, log-normal or triangle. The parameters of the PDFs were set by analysing the available data on emission factors and activity data or by expert judgement.
- If there was a lack of data for some emission source, associated uncertainties were extracted from the IPCC guidelines which imply that default uncertainty parameters were set.
- Using the software tool @RISK 5.7, each PDF was sampled 10,000 times and the emission calculations performed to produce a converged output distribution.
- The uncertainty in the trend between 1990 and the latest reported year, according to gas, was also estimated.

### **Uncertainty distributions**

#### A) Distributions

All of the input parameters in inventory are modelled using normal (95%), log-normal and triangle (some inputs in LULUCF) distributions.

#### B) Correlations

The Monte Carlo model contains a number of correlations. Omitting these correlations would lead to the uncertainties being underestimated.

The trend uncertainty in the Monte Carlo model is particularly sensitive to some correlations.

#### C) Activity data and emission factor uncertainty

If for activity data or emission factor uncertainty default value from IPCC guidance was used, average value from range of given uncertainty was set.

### Uncertainty in the emissions excluding LULUCF

The estimate of CO<sub>2</sub>-eq emissions in 2015 was estimated at 23,502.15 Gg CO<sub>2</sub>-eq.

The estimate of CO<sub>2</sub>-eq emissions in 1990 was estimated at 31,153.70 Gg CO<sub>2</sub>-eq.

Monte Carlo analysis shows that with a certainty of 95% we can say that the total emissions of categories for the year 2015 (23,708.63 Gg CO<sub>2</sub>-eq) according to simulation varies between 22,649 Gg CO<sub>2</sub>-eq (2.5% percentile) and 24,893 Gg CO<sub>2</sub>-eq (97.5% percentile).

Figure A2.1-1: Distribution of total CO<sub>2</sub> emission for year 2015 excluding LULUCF

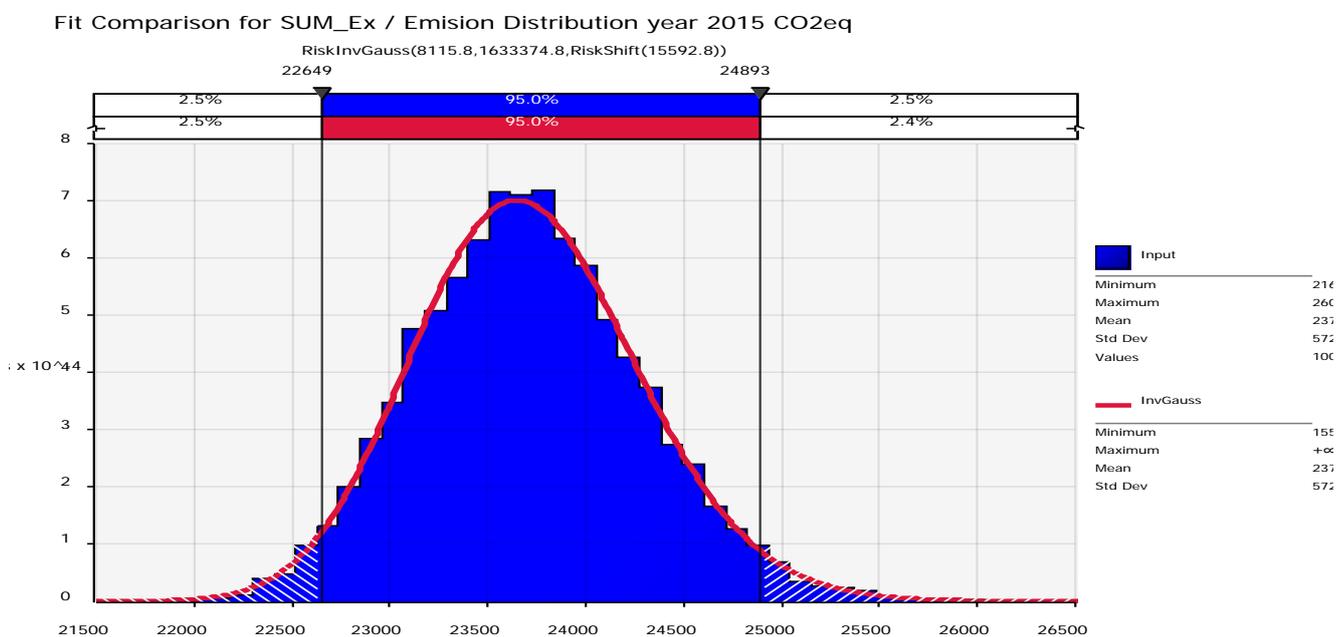

Figure A2.1-1 shows the distribution of total CO<sub>2</sub> emission for year 2015 with a corresponding probability density function (red line) that best matches the simulation results.

Monte Carlo analysis shows that with a certainty of 95% we can say that the total simulated emissions of all categories excluding LULUCF for the year 1990 (31,383.35 Gg CO<sub>2</sub>-eq) varies between 30,248 Gg CO<sub>2</sub>-eq (2.5% percentile) and 32,639 Gg CO<sub>2</sub>-eq (97.5% percentile).

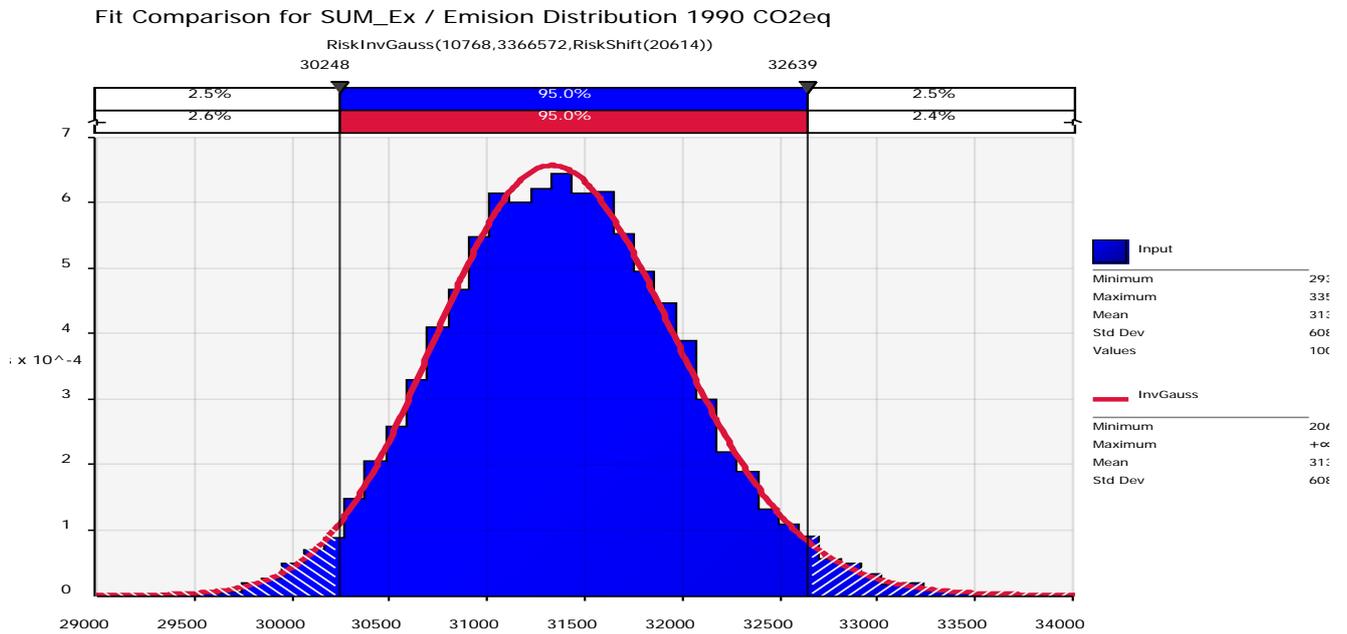

Figure A2.1-2 shows the distribution of total CO<sub>2</sub> emission for year 1990 with a corresponding probability density function (red line) that best matches the simulation results.

### Uncertainty in the trend excluding LULUCF

The trend in the inventory is estimated for each category and for the total summary emission (all categories included) with the following formula:

$$MeanTrend (\%) = \left( \frac{Year\ emissions - Base\ year\ emissions}{Base\ year\ emissions} \right) \cdot 100 .$$

The Inventory trend excluding LULUCF is -24.56%, simulated trend is -24.43 % and the 95% probability range of the trend is -28.76% (2,5% percentile) to -19.67% (97.5% percentile).

Figure A2.1-4: Distribution of total CO<sub>2</sub> emission for year 2015 including LULUCF

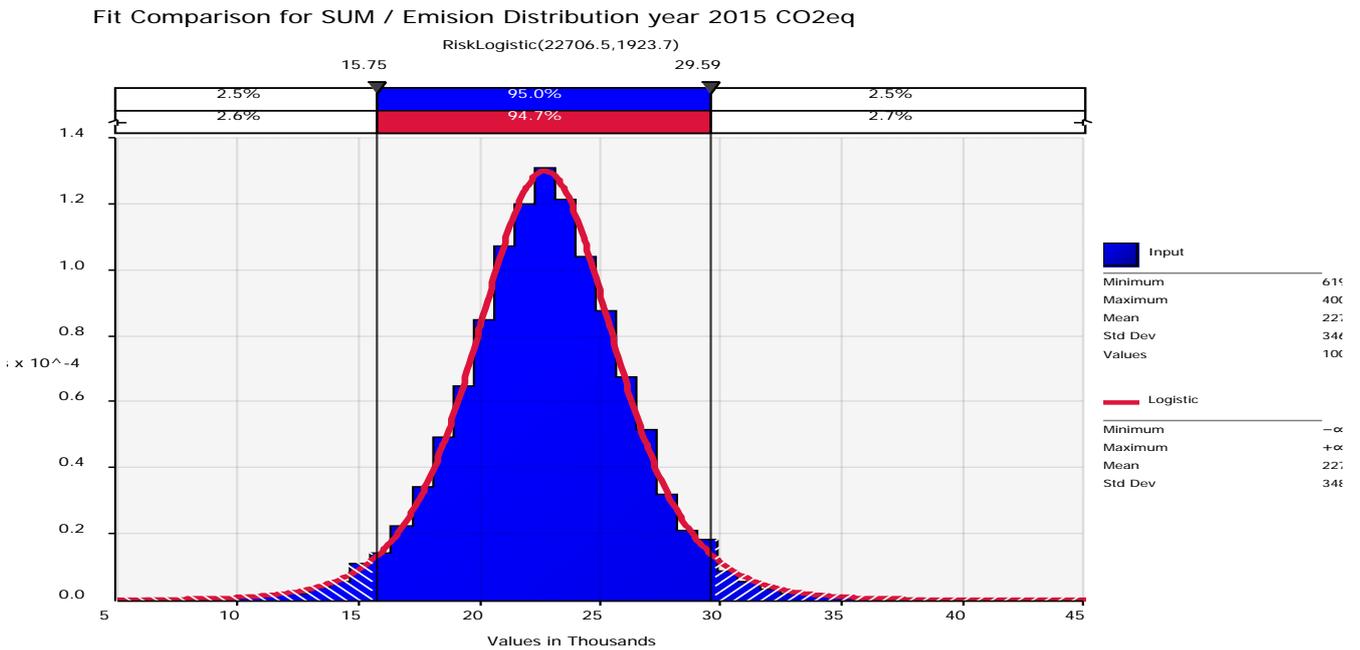

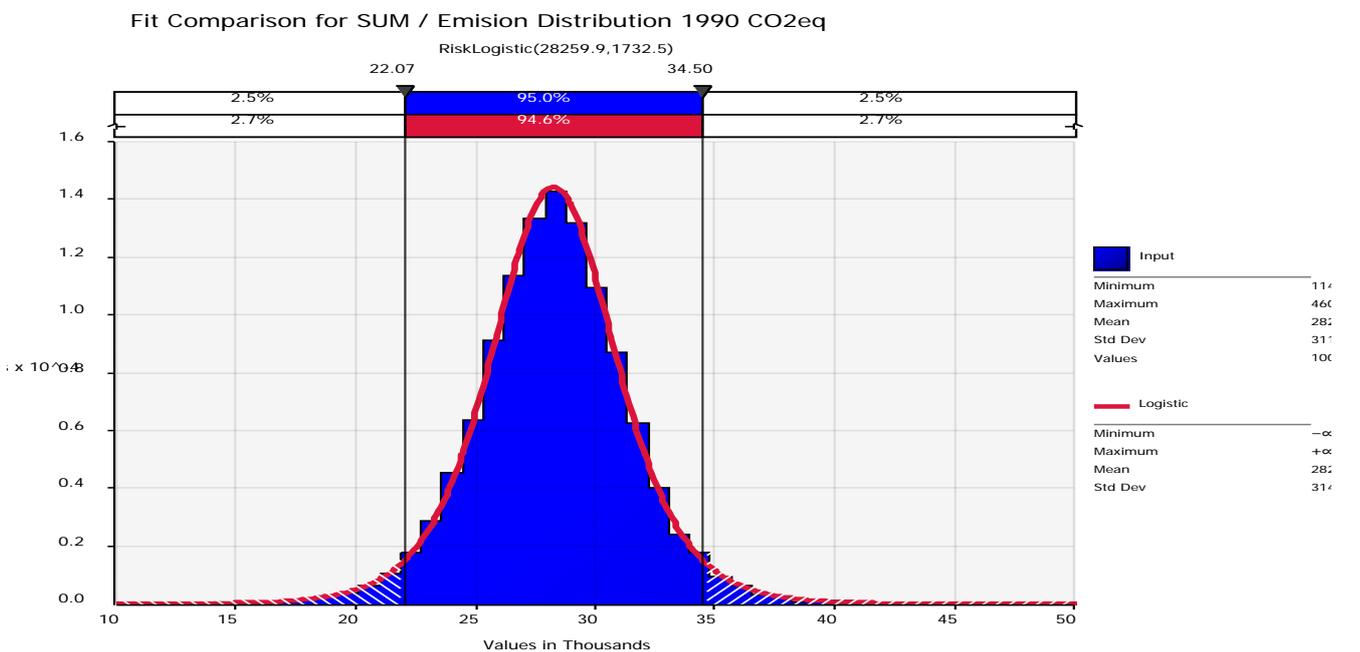

Figure A2.1-5: Distribution of total CO<sub>2</sub> emission for year 1990 including LULUCF

Monte Carlo analysis shows that with a certainty of 95% we can say that the total simulated emissions of all categories including LULUCF for the year 1990 (28,260.61 Gg CO<sub>2</sub>-eq) varies between 22,066.78 Gg CO<sub>2</sub>-eq (2.5% percentile) and 34,501.67 Gg CO<sub>2</sub>-eq (97.5% percentile).

Figure A2.1-5 shows the distribution of total CO<sub>2</sub> emission for year 1990 with a corresponding probability density function (red line) that best matches the simulation results.

### Uncertainty in the trend including LULUCF

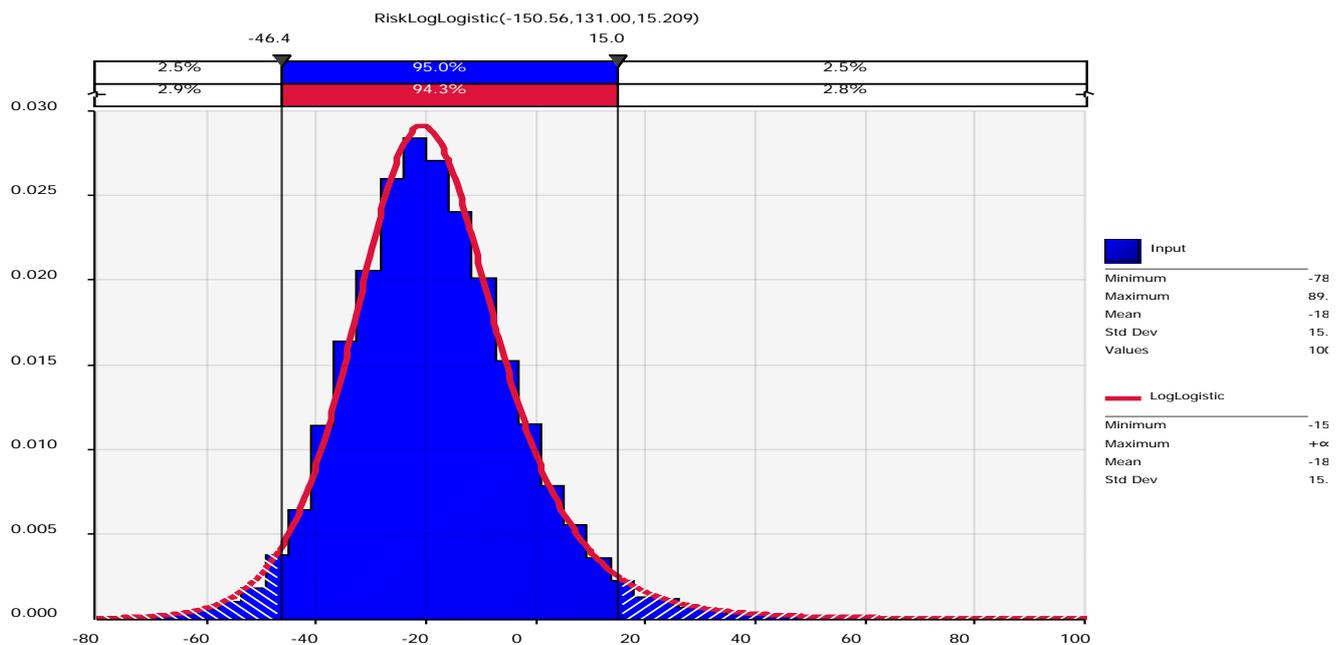

The trend in the inventory is estimated for each category and for the total summary emission (all categories included) with the following formula:

$$\text{Mean Trend (\%)} = \left( \frac{\text{Year emissions} - \text{Base year emissions}}{\text{Base year emissions}} \right) \cdot 100 .$$

The Inventory trend including LULUCF is -24,64%, simulated trend is -18.64% and the 95% probability range of the trend is -46.56% (2,5% percentile) to 14.97% (97.5% percentile), so the uncertainty introduced in trend varies from -21.91% to 39.62% with respect to the base year emissions.

Figure A2.1-6: shows the distribution of trend for year 2015 respect to year 1990 with a corresponding probability density function (red line) that best matches the simulation results, including LULUCF.

Approach and Comments:

1. A more complex method for estimation of uncertainties is used, and therefore activity data and emission factor uncertainties are left blank. Only combined uncertainty and trend uncertainty is shown in model.
2. Trend not calculated, when base year or year t emissions are zero or included elsewhere.
3. Combined uncertainty was used through Monte Carlo simulation for LULUCF sector
4. Different units of AD
5. Recovery included in estimation of GHG emissions
