

SIXTH ASSESSMENT REPORT

Working Group 1 - The Physical Science Basis

Presentation to the Warsaw International Mechanism Excom 14

Richard Jones, Coordinating Lead Author, Atlas

September 2021

#ClimateReport #IPCC

A decorative background image at the bottom of the slide, featuring a colorful, abstract map or satellite imagery with a color palette of blue, green, yellow, orange, and purple.

Outline

- **New AR6 WGI reference regions**
 - to better represent regional climate
- **Observed and future changes in extremes in all regions**
- **Climatic Impact-Drivers (CIDs)**
 - Physical climate information relevant to impact and risk assessment
- **Multiple and diverse CID changes in all regions**
- **The Interactive Atlas**
 - supporting the exploration of evidence and findings

New WGI AR6 reference regions

WGI AR6 Land and Ocean reference regions used in the report

46 Land regions
15 Ocean regions

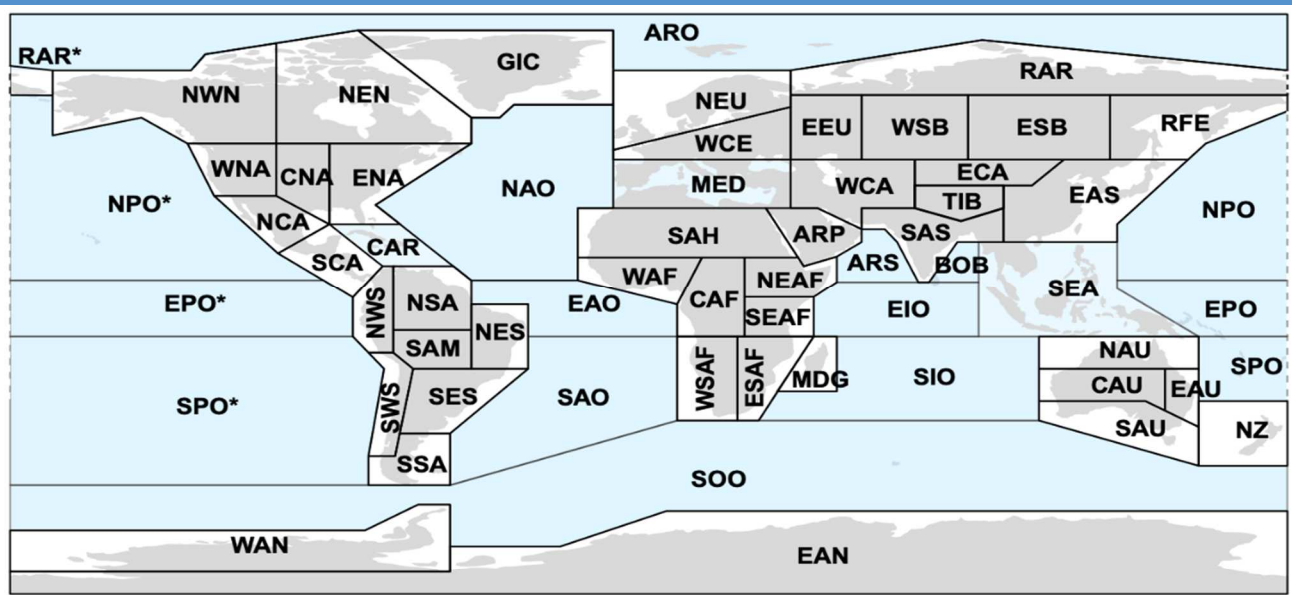

Improved regional climate consistency

Better representation of regional climate features

Regional statistics more representative of new higher resolution models

Refinement of earlier reference regions via broad consultation and peer review

“ It is indisputable that human activities are causing climate change, making extreme climate events, including heat waves, heavy rainfall, and droughts, more frequent and severe.

Climate change is already affecting every inhabited region across the globe with human influence contributing to many observed changes in weather and climate extremes

a) Synthesis of assessment of observed change in **hot extremes** and confidence in human contribution to the observed changes in the world's regions

Type of observed change in hot extremes

- Increase (41)
- Decrease (0)
- Low agreement in the type of change (2)
- Limited data and/or literature (2)

Confidence in human contribution to the observed change

- High
- Medium
- Low due to limited agreement
- Low due to limited evidence

Figure SPM.3

- Changes in hot extremes observed and attributed to human influence almost everywhere
- Many regions also experiencing increases in heavy precipitation and droughts

b) Synthesis of assessment of observed change in **heavy precipitation** and confidence in human contribution to the observed changes in the world's regions

Type of observed change in heavy precipitation

- Increase (19)
- Decrease (0)
- Low agreement in the type of change (8)
- Limited data and/or literature (18)

Confidence in human contribution to the observed change

- High
- Medium
- Low due to limited agreement
- Low due to limited evidence

c) Synthesis of assessment of observed change in **agricultural and ecological drought** and confidence in human contribution to the observed changes in the world's regions

It is *likely* that the global proportion of major (Category 3–5) **tropical cyclone** occurrence has increased over the last four decades. These changes cannot be explained by internal variability alone (*medium confidence*)

Human influence has *likely* increased the chance of **compound extreme events** since the 1950s:

- Increases in the frequency of **concurrent heatwaves and droughts** on the global scale (*high confidence*)
- Increase in **fire weather** in some regions of all inhabited continents (*medium confidence*)
- Increase in **compound flooding** in some locations (*medium confidence*)

Projected changes in extremes are larger in frequency and intensity with every additional increment of global warming

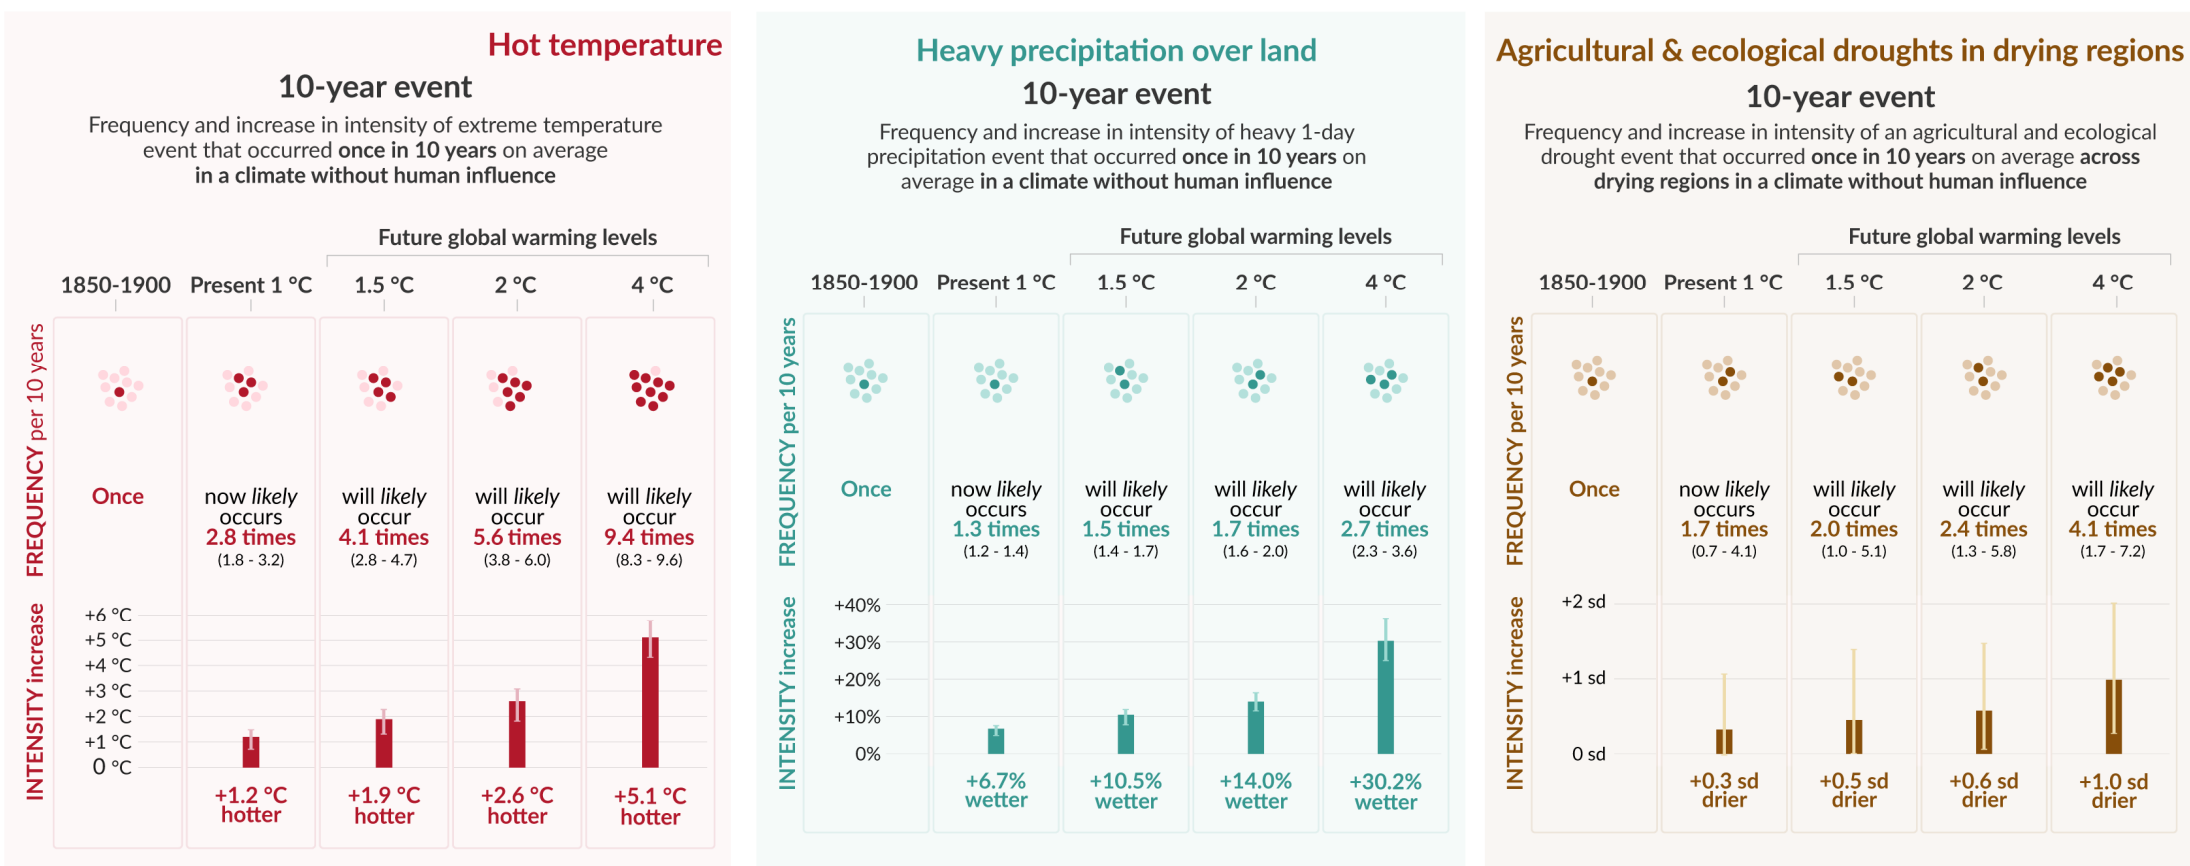

Figure SPM.6: Demonstrates extremes are already more likely and more intense due to current warming and these trends will continue with each additional fraction of warming.

Human influence has *very likely* warmed the global upper ocean since the 1970s and is *virtually certain* the main driver of current open ocean surface acidification.

Human influence is *very likely* the main driver of the global retreat of glaciers since the 1990s and mountain and polar glaciers are committed to continue melting for decades or centuries (*very high confidence*).

Continued ice loss over the 21st century is *virtually certain* for the Greenland Ice Sheet and *likely* for the Antarctic Ice Sheet.

Human influence was *very likely* the main driver of increases in global mean sea level since at least 1971.

Due to relative sea level rise, extreme sea level events that occurred once per century in the recent past are projected to occur at least annually at more than half of all tide gauge locations by 2100 (*high confidence*).

Sea-level rise projections

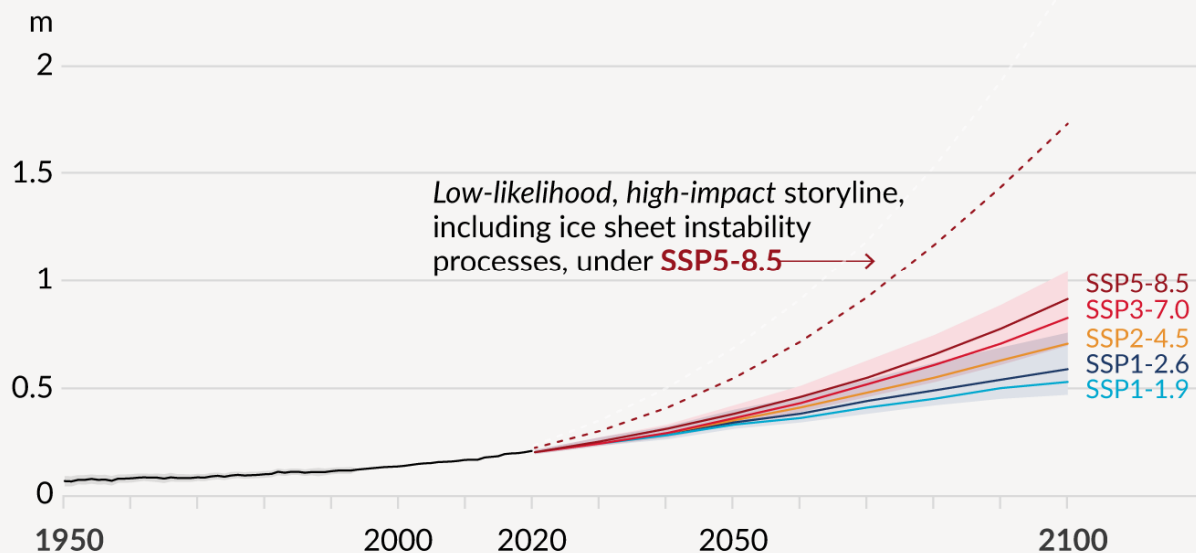

Figure SPM.8, panels d) and e):

- Sea levels will continue to rise this century even under the lowest emissions
- Increases between 0.5 and 1m are likely under the range of emissions considered
- Considering additional poorly understood but plausible processes (such as ice-sheet instability), much higher increases could occur
- Sea levels will continue to increase for centuries, even if warming stabilises

d) Global mean sea level change relative to 1900

d) Global mean sea level change relative to 1900

e) Global mean sea level change in 2300 relative to 1900

Sea level rise greater than 15m cannot be ruled out with high emissions

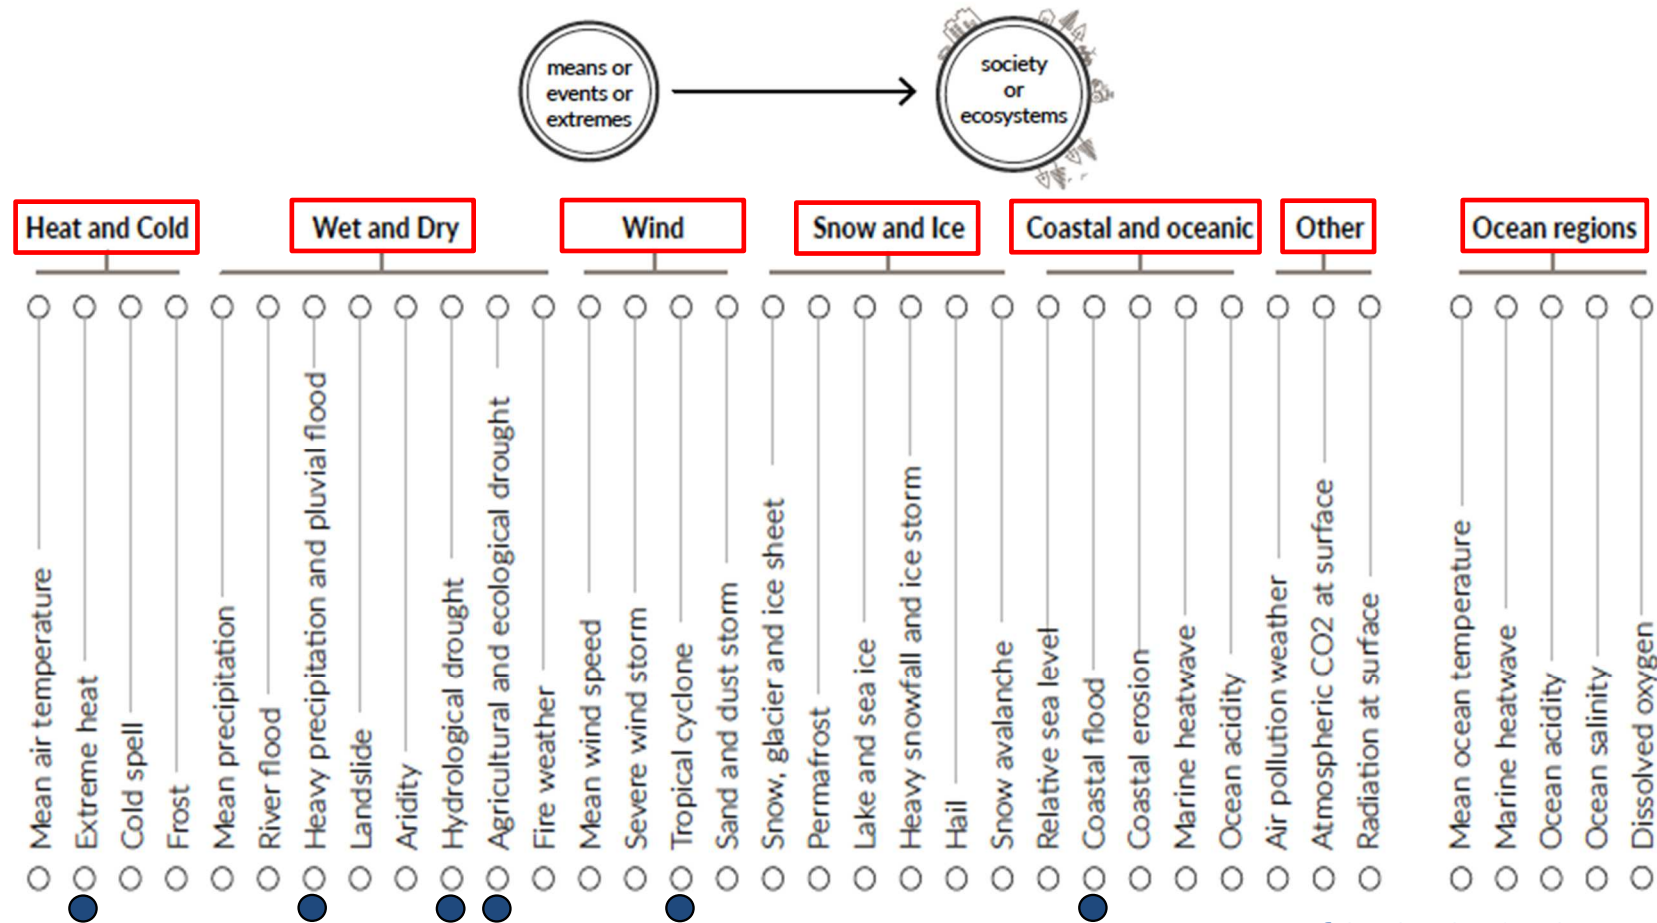

[Credit: Hong Nguyen | Unsplash]

“ Climate change is already affecting every region on Earth, in multiple ways.

The changes we experience will increase with further warming.

Climatic Impact-Drivers (CIDs)

Climatic Impact-Drivers (CIDs) are physical climate system conditions (e.g., means, events, extremes) that affect an element of society or an ecosystem. CIDs assessed were selected as relevant to impacts and risks.

CIDs include also extremes (examples shown assessed in Ch 11)

{CH8, CH9, CH11, CH12, Atlas}

Table TS.5

Number of land & coastal regions (a) and open-ocean regions (b) where each climatic impact-driver (CID) is projected to **increase** or **decrease** with **high confidence** (dark shade) or **medium confidence** (light shade)

Multiple climatic impact-drivers are projected to change in all regions of the world

interactive-atlas.ipcc.ch

Figure SPM.9

- Demonstrates that at least 10 CIDs will change in almost all regions (96%), and at least 15 CIDs in half of the regions
- Each region will experience a specific set of CID changes
- Each bar represents a geographical set of changes that can be explored in the Interactive Atlas

Interactive Atlas – Regional synthesis of changes in CIDs

SELECT VISUALIZATION

MAP
 HEXAGONS

HEAT AND COLD

- Mean air temperature
- Extreme heat
- Cold spell
- Frost

WET AND DRY

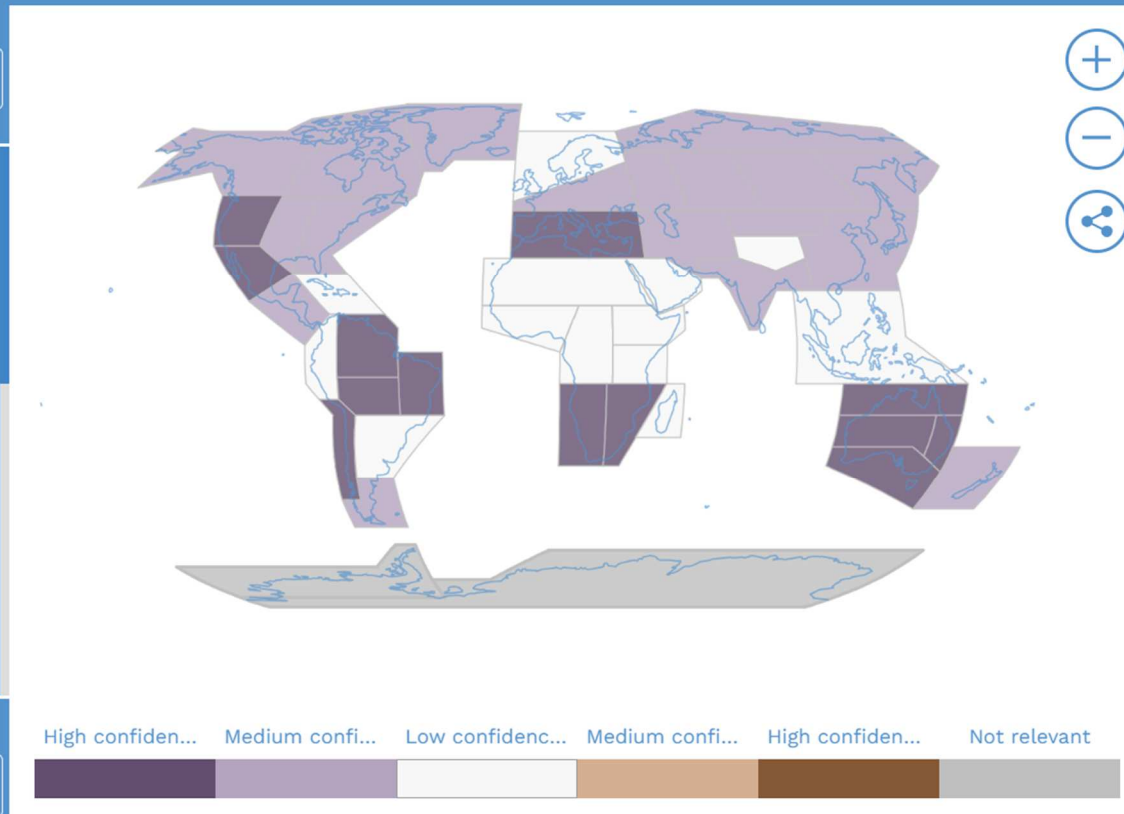

- Mean precipitation
- River flood
- Heavy precipitation
- Landslide
- Aridity
- Hydrological drought
- Agricultural drought
- Fire weather

WIND

- Mean wind speed

SELECT MAGNITUDE

PROJECTIONS
 TRENDS

Example view showing those regions where fire weather will change with high or medium confidence

Dark and light purple showing regions with increases;

Changes are low confidence in white areas;

CID is not broadly relevant in grey areas.

The **Interactive Atlas** allows for **flexible spatial and temporal analyses** of essential climate variables, extreme indices and climatic impact-drivers including multiple lines of evidence to support the assessment of regional climate change:

- **Observations**
- **CMIP5**
- **CMIP6**
- **CORDEX**, available for 12 continent-wide domains.

Regional (aggregated) information for reference and typological regions:

- (a) Time series
- (b) Stripes
- (c) Annual cycle plots
- (d) Global warming level (GWL) plots
- (e) Scatter plots (e.g. precip. vs temp.)
- () Summary tabular information

Dimensions of analysis include time periods for scenarios and global warming levels (1°C, 2°C, 3°C and 4°C).

Interactive Atlas – Regional information on changes in CIDs

Interactive Atlas regional information example views

(a) Main interface includes a global map and controls to define the specific dataset, variable, period (reference and baseline) and season (example is for annual temperature change from CMIP6 for SSP3-7.0, 2081–2100 relative to 1995–2104).

Regions can be selected on the map to bring up options for summary visuals or tables of regionally averaged information. Examples show:

- (b) evolution of temperature change using stripes;
- (c) Change in annual cycle
- (d) Change in selected CID at a range of global warming levels
- (e) Scatter plots of changes in two variables (e.g. temperature and precipitation shown here)

Thank you.
