FOREWORD

Technology transfer has been under focus since the Rio Summit in 1992, where issues related to technology transfer were included in Agenda 21 as well as in the United Nations Framework Convention on Climate Change.

Technology Need Assessment (TNA) project in Rwanda was intended to produce four main reports notably TNA, Barrier Analysis & Enabling framework, National Technology Action Plans (TAPs) and Project Ideas for each prioritised technology.

The review of the four reports was carried out at different levels. At the national level, the reports were reviewed by the TNA Steering Committee, National TNA Team members and other different stakeholders from the energy and the agriculture sectors. At the internationally level, the review was carried out by experts from Environment et Développement du Tiers Monde (ENDA) and UNEP Risø Centre.

The ultimate goal of these reports is to guide political decision makers and national planners on selected economic sectors with highest vulnerability characteristics to the effects of climate change. They further highlight most appropriate technologies which would support these sectors and the country in general, to mitigate or adapt to the effects of climate change.

On behalf of the Government of Rwanda, I thank all stakeholders from public and private sectors who participated in different consultation and validation meetings held to evaluate the selection and prioritization of the sectors and technologies. Their inputs were invaluable and deeply appreciated. Lastly, I extend my gratitude to the Global Environmental Facility (GEF) for providing financial support. I also thank the UNEP Division of Technology, Industry and Economics, the UNEP Risoe Centre and ENDA for their technical support and guidance.
EXECUTIVE SUMMARY

This second phase of TNA project is aiming at identification of main barriers hindering the transfer and diffusion of Climate Change mitigation and adaptation technologies. Prioritized technologies were presented in the previous TNA report-1 for both mitigation and adaptation as follows: a) small hydropower, geothermal-to-power, Lake Kivu methane combined cycle gas turbine, Plug-in hybrid electric vehicles and large solar photovoltaic for mitigation; and b) seed and grain storage, agro forestry, radical terraces, drip irrigation and rainwater harvesting for adaptation.

Identification of main measures to remove such barriers for mitigation technologies resulted in a group of solutions and actions linked to key elements of enabling frameworks and policies. These are related to the areas of trade, subsidies, tariff, tax, regulation, public investment, reference and demonstration projects assistance to investors and front runners but also early adopters of technologies. Particular attention was given to barriers related to the national macroeconomic conditions including: inadequate financial options, high initial investment costs, importation duties, limited access to loans and high interest rates.

Comparison of costs and benefits resulted in a clear conclusion of potential application and adoption of all prioritized technologies, especially the new ones expected to be introduced in near future for mitigation. These technologies include geothermal, hybrid electric vehicles and large solar PV.

In addition to the fact that all the prioritized mitigation technologies fulfill the key criteria of national priorities up to 2020, the target of GHG mitigation is expected from a diversification approach relying on, among others, exploitation of all available and sustainable energy resources. This is why the Lake Kivu methane gas is expected to play an important role in such a project in case carbon capture and sequestration is taken as an option.

Barrier analysis for the adaptation technologies was also conducted. The following were identified as main barriers which would hinder the transfer and diffusion of adaptation technology options: High initial investment costs, limited technical knowledge, limited awareness about long term benefits of some of the technologies, limited access to funds and high interest rates. It was also found that conducive enabling environments exist which may ease the transfer and diffusion. These include but not limited to: Existence of institutional policies, strategies and political will to subsidize raw agricultural inputs as well as provision of incentives.

Barrier analysis and enabling framework report
CHAPTER 1: ENERGY SECTOR

1.1 Preliminary Targets for Technology Transfer and Diffusion

Within the context of climate change mitigation and TNA project, targets for deployment of prioritized technologies are guided mainly by official documents such as the National Energy Policy and Strategy (MININFRA, 2012), the Rwanda Vision 2020 and the Millennium Development Goals (UNPD, 2005).

For any support to socio economic growth and poverty alleviation, sustainable and affordable energy technologies are required. As presented below the case of Rwanda is really crucial if we refer to some key indicators showing that the level of modern energy consumption is still very low. The annual per-capita primary energy consumption is only 0.17 toe (tonne oil equivalent) in Rwanda against 0.16 toe in sub-Saharan Africa and 4.7 toe in industrialized countries (IMF, 2008). For the case of other Sub-sectors of energy consumption (petroleum, electricity), Rwanda is also still lagging behind. Therefore, the targets below are aiming at improving the status quo so that at least 50% of the population can have access to electricity by the year 2017. As a whole, the cost estimates for the funds required for implementation of the accelerated least cost generation mix from 2011 to 2017 is 5,274 Millions USD.

Regarding the particular sub-sector of electricity, we consider the increase of electricity capacity as a central target and expected outputs are as follows:

- Annual per-capita electric capacity from 5 kW in 2008 to 113 kW in 2020;
- Annual per-capita electric energy from 23 kWh in 2008 to 488 kWh in 2020;
- Rate of access to electricity: from 6% in 2008 to 50% in 2020

The targets above in electricity energy usage are crucial as Rwanda is still lagging behind in the matter of electricity services. While for instance in Sub-Saharan Africa and in developed countries, average annual per-capita electricity consumption was respectively 478 kWh and 1200 kWh in year 2008; such gaps are still valid up to now.

1 All preselected technologies presented in the previous TNA report are feasible options at short/medium term in the context of the timeframe up to year 2030 and mainly through the diversification approach. Within the context of national energy policy for goals up to 2017 in addition to the ranking process and criteria mentioned in TNA report, this stage of barriers analysis is limited to only five options: geothermal, Kivu methane CCGT, hydropower, solar and Plug-in hybrid electric vehicles.
2 Such total capital cost are expected to cover mainly the least cost generation of energy, electrification, petroleum storage, transmission lines, efficiency, biomass conservation and also capacity building.
3 Per-capita electricity consumption is therefore in sub-Saharan Africa 21 times more important (compared to Rwanda); in developed it is about 60 times more.
1.1.1 Specific targets in geothermal up to 2017

- Assessment of geothermal resources mainly in the volcanic northern areas and along the whole portion of Rift Valley from the north to the south-West of the country;
- Installation of a pilot project plant of 10 MW;
- Generation of about 310 MW of electricity power by the end of year 2017;
- Identification of private investors and partners for financial support.

1.1.2 Specific targets for Kivu methane gas

- Based on the successful 3.6 MW Kivu methane pilot project plant operational since November 2008, negotiate and establish agreements with private sector and international investors for funding projects of 20 MW to 50 MW;
- Installation of about 300 MW by the end of 2017 mainly by private promoters under support by the government agencies and donors;
- Negotiation between the governments of RD Congo and Rwanda for developing a joint 200 MW power plant based on methane gas;
- Liquefaction of methane gas for further replacement of biomass and diesel fuels used in households and industry sector4.

1.1.3 Specific targets for small-hydropower

- Promotion of private sector participation in hydropower production at large and small scales;
- The delivery of licenses for small hydropower projects;—
- Exploitation of a higher number of small hydropower sites so that additional 75 MW can be installed between 2011 and 2017;
- Promoting the legal and regulatory frameworks of micro-hydropower and mini grids under the monitoring of EWSA ;
- Financing and investing through IPP (Independent Power Producers) negotiation between EWSA and local promoters and community–based associations or cooperatives.

---

4 Liquefied methane gas (in addition to biogas, solar water heaters, biofuels, electricity) is greatly expected to contribute in reducing biomass use from 555 to 3000 kg-oil-equivalent, respectively from year 2008 to 2020. (MININFRA, 2012)
1.1.4 Specific targets for PHEV

- Increasing the capacity of transport sector
- Substituting imported petroleum fuels by methane gas converted into liquid fuels
- Developing a market based on efficient gasoline cars
- Introducing the green transport through the use of biodiesel and deployment of electric vehicles

1.1.5 Specific targets for solar PV

- Development of a national strategy for operation and maintenance of large solar PV system
- Exempting all types of solar equipments and components from import duties;
- Basic electrification of all schools, all health centers and all administrative offices in remote rural areas;
- Based on lessons learnt from the 250 kW pilot plant installed near Kigali at Mount Jali, replication and installation of solar PV connected to the national EWSA grid;
- Development of guidelines on sizing and tender for provision of solar systems with high quality standards.

1.2 Methodology and Guidelines

Our methodology, used in the identifying of barriers to acquisition and deployment of energy technologies, in the specifying of appropriate measures and enabling frameworks to succeed in the process of transfer and diffusion, will be influenced by characteristics of targeted technologies. New technologies can obviously require a preliminary phase of share of information about their popularity in developed countries. Inventory for further sustainability of energy resources is also essential.

With reference to guidelines and handbooks designed and published by UNDP and World Bank (UNDP, 2010; ESMAP, 2007), barriers hindering transfer and diffusion of energy technologies can be classified into four main categories: technological, financial, economic and institutional. For each selected and prioritized technology, barriers, measures and frameworks will be identified, analyzed and discussed through consultations with stakeholders expected to play a key role in all phases of the TNA project in Rwanda.

Such adequate procurement can also take into account new solar products more efficient like concentrated solar photovoltaic (CPV)
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

According to the observations recorded in countries where our targeted energy technologies have been successful, the range of barriers to transfer and diffusion is large and covers the following issues: a) commercial and competitive aspect, b) skills and knowledge, c) availability of technology products, d) initial capital cost and total production cost, e) institutional framework, f) involvement of the investors and banks, g) access to loans and subsidies, h) access to the national grid and agreements between EWSA as a national utility and private developers, i) type of settlements in rural areas for population, j) importation of products and energy fuels, k) preference in using traditional wood fuels. For better reading, a simplified route cause analysis (diagram of causes, barriers and impacts) will be done for each technology i-e problem tree methodology (refer to annex-I). For each technology, the problem tree will be translated into the solution tree reflecting the transformation of causes into actions to removal of barriers and effects of barriers into results of measures.
1.3 Barrier Analysis and Measures for Large Solar Photovoltaic (PV) Technology

1.3.1 General description of technology

The initial research in PV technology proved that special material of semiconductors convert the sunlight directly into electricity. The process of preparing such materials requires about 1,400 °C. This is why, among other reasons, PV systems are expensive. Worldwide production was only 5 MW in the year 1982 and substantially increased to 385 MW in year 2001. These trends regard mainly small-scale solar PV.

In fact, large grid-connected solar PV technology is relatively new, but highly promising. Solar radiation globally produces about 5 kWh every day per square meter of a receiver surface. Conditions for a proper production of electric power directly connected to national grid, or any mini-grid, are complex. This is due to required agreements between EWSA and the private sector that is expected to invest in large-scale PV systems with 5 MW capacity or more. Characteristics of a 5 MW solar PV plant based on a modular unit of 73 kW [http://www.caddet.org] are roughly as follows:

- PV area: 532 m²
- PV efficiency: 14%
- Inverter efficiency: 85% (DC to AC)
- Total incident radiation: 526 MWh/year
- Total incident: 55 MWh/year; such a modular unit can result in a larger PV plant once about 70 units are assembled and can provide 5 MW

Connection to the national grid is more appropriate for reducing the cost by avoiding the use of batteries. Thus, the capacity factor equals the daily sunshine duration (in Rwanda about 6 hours). Lifespan of main components is 25 years. There is an optional scenario for reduction of cost involving concentrating solar energy in order to use less size of solar modules (i.e. requirements of about 5 kWh/m² for the beam direct normal solar component).
1.3.2 Identification of barriers to deployment of large solar PV

1.3.2.1 Economic and financial barriers

The causes of absence of development and introduction of large solar PV technology are as follows: High initial capital cost of solar product and batteries, fluctuations and inflation affecting the costs of equipments, investors and local developers are not attracted. Skilled expertise is missing for setting up frameworks related to, for instance, agreements with EWSA for reduction of costs through a direct connection to national electric grid. Another constraint is related to inability to apply research and adopt new options like concentrated photovoltaic and organic solar cells. The deployment of large solar PV system is also limited by the inexistence of pilot projects for further demonstration beyond the phase of research and development. One of the adverse impacts is the limited diversification of electric energy sources in Rwanda and low exploitation of such a clean resource.
Table 1: Economic and Financial Barriers

<tr>
<th>Barriers</th>
<th>Elements of barriers</th>
<th>Presentation and dimensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limited penetration into the market</td>
<td>High Initial Capital Cost</td>
<td>The Photovoltaic system compared to other commercial energy technologies remains very expensive; Subsidies and low taxes have not yet resulted in larger diffusion of PV modules in Rwanda; Only some institutions (schools, health centers) can just afford an installation of about 3kW for mainly lighting purposes; EWSA installed just only a small plant with a capacity of 250 kW in Rwanda, near Kigali.</td>
</tr>
<tr>
<td>Limited access to loans from banks and leasing programs</td>
<td>Acquisition of solar modules is limited by the initial capital cost which has to be paid for in cash; Lack of access to credit is limiting both investors and end users to small scale size of solar products.</td>
<td></td>
</tr>
<tr>
<td>Weak network and limited update of information on solar products</td>
<td>Poor knowledge in PV sector results in buying non tested solar modules as of now and then, second hand products are taken as new on the local market; new equipments remain expensive; In addition, imported products from Europe, China, USA or Japan to Rwanda,( a landlocked country) are quite expensive due to transport and transaction costs.</td>
<td></td>
</tr>
<tr>
<td>High cost installing private grids</td>
<td>Absence of decentralized mini-grid for distribution of electricity energy is limiting deployment and diffusion of large solar PV system.</td>
<td></td>
</tr>
</tbody>
</table>
1.3.2.2 Non Financial barriers

Table 2: Non Financial Barriers

<table>

<tr>
<td>Imperfection of solar market</td>
<td>Non-existent local industry for solar</td>
<td>An initiative of assembling the solar modules was set up before 1993 in Kabgayi headquarters of Catholic Church; it is no longer operational while it was expected to play a key role in making solar cells more known and popularised.</td>
</tr>
<tr>
<td>Unfamiliarity with solar PV technology</td>
<td>Design, preparation and implementation of any solar PV project, especially for larger scales, require more skilled labor and expertise which are currently missing for Rwanda; among others, more special skills in setting up local mini-grids are missing; all phases of installation, operation and maintenance have to refer to information on solar resources (variability within the year).</td>
<td></td>
</tr>
<tr>
<td>Low competitiveness</td>
<td>From schools and universities to stakeholders’ relative low awareness to solar PV technology, especially for large scale size, is noted; this option is found useful only for very small application of lighting just like the option of simple batteries charged at any available station. Compared to ordinary supply of energy from EWSA, the solar PV is less practical. Power generated is low while its cost of acquisition is high.</td>
<td></td>
</tr>
<tr>
<td>Access to enough land</td>
<td>Due to the limited efficiency of converting solar light into electricity, large land areas are required for installing a large solar PV. Rwanda has the highest density of population in Africa; a situation that renders this application very challenging.</td>

Barrier analysis and enabling framework report

19
large solar PV plants are very few in Rwanda.

Expert skills development to properly design and plan for the development and diffusion of the large solar PV systems needs more focus.

The technical benefits from the use and installation of the large solar PV and connection to the EWSA grid are not yet understood; the small sizes are better known and therefore more popular in Rwanda.

<td>Crucial</td>
</tr>
</tbody>
</table>

The urgent measures to overcome barriers to diffusion of large solar PV are mainly those which are regarding the higher ranked barriers classified as:"important", “crucial’ and “killer”. Therefore a special fund via the carbon credit market, subsidies, feed-in-tariff and capacity building are recommended. A particular centre for promoting the installation and deployment of large solar PV system is required.
For instance, based on experience and lessons from advanced countries, feed-intariff is a successful influence on deployment of large solar PV system. In Germany about 75% of installed PV capacity received such a tariff support (Rickerson et al, 2010). Instead of EWSA relying on the very small solar PV (250 kW), it is highly recommended to install a larger plant for further demonstration and replication where suitable at a faster pace.

1.4 Barrier Analysis and Measures for Small Hydropower (SHP) Technology

1.4.1 General Description of Technology

The small hydropower technology is a well known mitigation option and suitable for both remote areas and wider distribution through national grids. It is characterized by the following issues:

- The hydropower sector is playing a great role in economic development since the last decades of the 20th century,
- The production of hydro-electricity is based on a simple conversion of water potential energy into electricity by a combined system of water turbines and generators;
- Efficiency of conversion is relatively high, about 60%,
- Use of the Manning equation for designing small hydroelectric power systems driven by water flowing through pipes i.e steel or PVC or concrete penstocks,
- For power capacities less than 600 kW, installed transformers can be very small
- Hydraulic turbines’ efficiency: 80%, generators: 90% and transformers: 90%,
- Option of in-stream turbine is appropriate for low lands like in Western Province of Rwanda,
- Design based on the Kaplan or Francis Turbine; self excited induction for pico-hydropower,
- Amount of electricity power is proportional to the head drop and the water flow discharged on turbine,
- Pico-hydro: lifespan is about 15 years,
- Micro-hydro: lifespan is about 30 years,
- The capacity factor i.e. operational time duration per day: about 50% or more according to the local conditions and the size of the demand,
- Power capacity: less than 50 kW for a pico-hydro system and less than 1 000 kW for a micro-hydro plant,
- The electricity output is linked to seasonal variations of water flow and specific designs.
1.4.2 Identification of barriers

1.4.2.1 Economic and financial barriers

Table 5: Main economic and financial barriers

<table>
<thead>
<tr>
<th>Barriers</th>
<th>Elements of barriers</th>
<th>Presentation and dimension</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limited financial facilities</td>
<td>High cost of equipment</td>
<td>Due to the absence of local industries for electronics and electro-machinery, equipment for hydro plants is imported.</td>
</tr>
<tr>
<td>Limited financial capacity of private sector</td>
<td>The number of private investors in energy sector and particularly in power production, supply and distribution is still low due to limited financial capacity</td>
<td></td>
</tr>
<tr>
<td>High cost of construction and installation</td>
<td>Due to, among other, the morphology, topography and land slope, construction of small hydropower plant is expensive; it seems to be the case for instance for new project of Rukarara (8 Megawatt) in the southern province and Keya (2.2 Megawatt) in Northern-West Rubavu district.</td>
<td></td>
</tr>
<tr>
<td>Low access to loans</td>

<th>Measures</th>
<th>Hierarchy of Barriers</th>
</tr>
</thead>
<tbody>
<tr>
<td>High cost of equipments</td>
<td>Promotion of industrial units for manufacturing appropriate steel-pipes instead of importing them (from Tanzania for instance) and for electrical components like transformers and generators but also water turbine for pico and small scales.</td>
<td>Important</td>
</tr>
<tr>
<td>High cost of construction and installation, and of preliminary studies</td>
<td>Reinforcement of local expertise and capacity building for high quality in designing small hydropower plants in mountains with high slope and varied geological structure</td>
<td>Crucial</td>
</tr>
<tr>
<td>Limited financial capacity</td>
<td>Set up a specialized service facility to access loans focusing on wider development of small hydropower plants; Set up a particular insurance scheme for hydrological risk related to climate change impacts and variability in water resources</td>
<td>Crucial</td>
</tr>
</tbody>
</table>

#### 1.4.3.2 Non financial measures

**Table 8: Non financial measures**

<table>
<thead>
<tr>
<th>Elements of Barriers</th>
<th>Measures</th>
<th>Hierarchy of Barriers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluctuation of water resources</td>
<td>More share and dissemination of information on hydrological changes and risk of damaging the hydropower plants;</td>
<td>Important</td>
</tr>
<tr>
<td>Limited skilled expertise (in fact, studies and preliminary design require a multidisciplinary team of)</td>
<td>Set up an appropriate and specific unit for training in renewable energy sector and hydropower engineering.</td>
<td>Important</td>
</tr>
</tbody>
</table>
The most important barrier to remove is the limited financial capacity of private promoters of small hydropower in Rwanda. Thus, subsidies and acceptable interest rates for payment of loans are the most useful measures for such a technology. Reduction of costs of equipment and maintenance is expected from among other application of specific measures like establishment of a local manufacturer for key equipment as mentioned in the above table.

1.5 Barrier Analysis and Measures for the Combined Cycle Gas Turbine (CCGT)
1.5.1 General Description of Technology
The CCGT plus an optional CCS technology is applicable to the Kivu methane gas in consideration of the following conditions:
- Small amount of Kivu methane gas under extraction since the 1950s for the heat purposes of the brewery BRALIRWA located in the North-West at Gisenyi town in Rubavu District;
- Annual supply: about 1.5 million cubic meters;
- Properties of the gas: mix of CO₂ and CH₄;
- The CCGT is not yet applied in Rwanda; it is also the case for the CCS,
- The CCGT is a combined use of a set of components: gas combustor, gas turbine, heat recovery boiler, steam turbine. It is a reliable commercial technology.
- The speed of methane resources regeneration rate is relatively limited. The planned speed of extraction can be adjusted to such a process of transformation resulting in renewability of methane gas.
- An amount of air and the methane gas are introduced in a combustor and burned.; The Gas Turbine, driven by gases from a combustor, is mechanically connected to the electric generator. Both heat and electricity are produced.

Such a use of both the gas turbine and steam turbines is commonly named: Combined Cycle Gas Turbine (CCGT). Modular units may range from 1 MW to 10 MW.

How does a CCGT work with both combustion gas turbine and steam turbine?
The methane gas is injected into a combustion chamber and burned. The exting expanding gases drive a gas turbine mechanically connected to a generator for producing electric energy. The waste heat is extracted from the gas turbine and sent to a boiler for producing
steam (Heat Recovery Steam – Gas Turbine). The steam, in turn, rotates a turbine (ST) connected to a generator. Specific parameters for a CCGT system are thermal efficiency: 34% for a gas turbine technology and 51% in case of a CCGT. Combustion gas turbine inlet temperature is 1300 °C while steam turbine inlet temperature is 538 °C. The capacity factor of the CCGT is 80% (i.e. 19 hours) and life span is 25 years.

The CCS is a set of components with roles of separation and extraction of CO₂ from the CCGT flue gases, its compression and transportation through the pipelines towards a geological system or water body as a final destination for storage.

<tr>
<td>Conflict with the green policy</td>
<td>Implementation of carbon credit market for applying the CCS scenario</td>
<td>Crucial</td>
</tr>
</tbody>
</table>

Given that a pilot project on Kivu methane-to-electricity power has been installed and is operational since 2009, deployment of CCGT technology requires a special fund for initiating the combined cycle approach. While it is crucial to overcome the barriers related to the issues of costs, it is highly recommended to solve the problem of liquefaction and that of distribution of methane far from the station of production.

1.6 Barrier Analysis and Measures for PHEV Technology

1.6.1 General Description of Technology

A plug-in hybrid electric vehicle (PHEV) is equipped with a conventional internal combustion engine and an electric motor. A battery rechargeable through any electric power station runs the electric motor while the combustion engine depends on fossil fuels or biofuels. In case of fossil fuels, efficient gasoline option is more recommended. For such a technology combining the two sources of energy, the amount of CO$_2$ emissions is lowered due to the decreased rate of fossil fuel consumption.

The source of electricity to which the battery plug is connected for recharging is expected to be a grid preferably based on hydropower, solar, wind and any other non carbon technology. For a recharging frequency of at least 2 times per day, PHEV consumes about 3 liters per 100 km against 4 liters in case of frequency of one charging per day. The overall efficiency of the system “Battery-Electric Motor-Wheels” transforming the chemical into mechanical through
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

electrical is about 75%. The efficiency of an internal combustion engine is about 15% in urban areas and 25% in rural or highways.

1.6.2 Identification of barriers for PHEV

Like any other technology, transfer and diffusion of PHEV in Rwanda will be faced mainly with barriers related to resistance to change, market failure, limited demand including low financial and purchase capacity. National policy and provision of incentives for such a transport innovation are also needed. Appropriate loans from the banks and leasing programs are also required for promoting the PHEV technology option. Another constraint would be the inexistent infrastructure for recharging batteries. Reference and pilot projects for a further deployment of PHEV alternative in Rwanda are also missing. For better implementation of GHG mitigation objectives, a diversification approach policy based on efficient gasoline-powered vehicles and electric power, is needed.
### 1.6.2.1 Economic and financial barriers

1.7 Barrier Analysis and Measures for Geothermal

1.7.1 General Description of Technology

By the year 1870 there was discovery of the role of radiogenic heat generated by long-lived radioactive isotopes of Uranium, Thorium and Potassium. In 1942, installed capacity of worldwide geothermal-electricity reached 127 MW as compared to 9,028 MW in year 2003. Geothermal exploitation follows a substantial investigation and exploration before deciding on the type of technology. There are 2 types of technology: Engineering Geothermal System (Hot Dry Rocks) or Naturally Hydrothermal Resources (Wet Rock Technology);

Once a sustainable reservoir of geothermal resources is discovered and drilled whole wells are properly installed, geothermal water brine, at about 180°C and pressure of 8 atmospheres, is extracted. A heat exchange system playing the role of transfer of heat to any selected working fluid is also installed.

- A steam turbine, driven by a heat working fluid, is connected to an electric generator. A system of conventional condenser and cooling tower fulfills the properties of thermodynamic cycle. Finally, the underground geothermal field is recharged through a reinjection at about 1 km from the position of the drilled whole wells.
- A binary hydrothermal electric power option is based on 2 fluids (1. geothermal steam/brine and 2. hydrocarbon working heat fluid)
- Working fluids: Kalina water-ammonia mixture; butane; n-pentane
- Capacity range: 200 kW to 20 MW
- Temperature required for the geothermal water brine is about 120 °C to 170 °C
- Flow of fluids: mode of a closed-loop in order to minimize GHG emissions
- Modern drilling can reach a depth of 10 km underground
- Average geothermal gradient: 3 °C/100 m
- Binary plants are elaborated for commercial purposes in small modular units
- For instance in Ethiopia, the installed geothermal-electric power was 8.5 MW in year 2003 against 45 for Kenya; up to now, leading countries are mainly USA (2 800 MW), Philippines (1 905 MW), Italy (862 MW),...
- In case of geothermal resources reaching a temperature higher than 180 °C and a pressure up to 8 atmospheres or more, the geothermal steam can be directly passed through the turbine connected to the generator; then it is condensed and re-injected into deep layers of ground for the recharging purposes; such an avoidance of use of a heat exchanger and a hydrocarbon working heat fluid makes the geothermal technology cleaner without
emission of GHG; instead, for lower temperatures and pressures, the steam is still containing the brine, thus a use of a heat exchanger and a hydrocarbon fluid is required.

### 1.7.2 Identification of Barriers to geothermal technology

#### 1.7.2.1 Economic and financial Barriers

**Table 17: Economic and financial Barriers**

<table>
<thead>
<tr>
<th>Barriers</th>
<th>Elements of barriers</th>

<tr>
<td>Conflict with owners of lands</td>
<td>Involvement of land owners in sharing the exploitation of geothermal</td>
<td>Important</td>
</tr>
</tbody>
</table>

Measures, actions and solutions expected for removal of economic and financial barriers are linked to a set of financial inputs. They are to be considered from the beginning of the geothermal exploration and cover the crucial cost of drilling and installing of equipment. It is recommended to enhance the capacity building for further establishment of a research and development facility and future management of the pilot –plant project (10 MW). Risk management of potential damage to the proposed plant should also be considered.
### 1.8 Linkages of Identified Barriers for the Energy Sector

Apart from the small hydropower, all these prioritized technologies are almost new in Rwanda and require a substantial phase of RDD (research-development-demonstration). There is also a common limitation in a database on energy resources’ distribution and availability.

The PHEV barriers are, among others, linked to the low level of deployment of renewable energy technologies.

**Table 21: Analysis of Linkages of Barriers for the Energy Sector**

<table>
<thead>
<tr>
<th>Type</th>
<th>Barriers</th>
<th>Linkages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Economic and Financial</td>
<td>High initial capital cost</td>
<td>Special attention has to be paid to technologies requiring particular equipment due to their costs for acquisition and installation (case of drilling and wells for geothermal; solar collectors; methane and its distribution after liquefaction).</td>
</tr>
<tr>
<td></td>
<td>Low access to loans for investing in energy sector</td>
<td>All technologies are sharing such a financial constraint. Small companies are facing this problem more especially for the case of new technologies (CCGT and CCS; geothermal; PHEV). The interest rate is high and a preliminary condition of having a guarantor are constraints common to the diffusion of all these prioritized options.</td>
</tr>
<tr>
<td></td>
<td>-High cost of fuel -High Operation and Maintenance costs</td>
<td>Cost of fuels like biomass and petroleum is high due to limitation in their resources and also their transport from the unit of preparation and treatment to the site of the power plants or centre of consumers.</td>
</tr>
<tr>
<td></td>
<td>Cost of access to lands and wetlands</td>
<td>Technologies facing such a problem are mainly those requiring large size of land for extracting or collecting energy fuel (geothermal; reservoirs for hydropower) or for</td>
</tr>
<tr>
<td>Non Financial</td>
<td>Financial</td>
<td></td>
</tr>
<tr>
<td>---------------</td>
<td>-----------</td>
<td></td>
</tr>
<tr>
<td>High cost of exploitation for access or extraction of fuel</td>
<td>installation of the power plant (large solar PV; solar CSP). For some technologies (geothermal, large hydro) arable land is allocated to power plants and this can lead to potential conflicts with the agricultural sector.</td>
<td></td>
</tr>
<tr>
<td>High cost of storage of energy resources and output products</td>
<td>Particularly geothermal and Kivu methane are characterized by high cost of extracting and collecting the intake resource; drilling for the geothermal can require a depth of wells reaching about 3 km and reinjection wells are separated by about 1 km.</td>
<td></td>
</tr>
<tr>
<td>Lack of legal statute for promotion of independent or mini-grid connections</td>
<td>Imported petroleum products, Kivu methane gas -to -power production for industry and cooking, heat energy produced by solar concentrators require large capacity of storage.</td>
<td></td>
</tr>
<tr>
<td>Limited local industry for electro-mechanics</td>
<td>Small scale power technologies like solar PV, micro-hydropower are especially affected by such a constraint to transmission, diffusion and distribution of remote power generated; more appropriate facilities are required for attracting private investors and communities.</td>
<td></td>
</tr>
<tr>
<td>Limited human and institutional capacity</td>
<td>All systems of electric power generation require basic equipments which are (almost if not all) imported for the case of Rwanda. One can name turbines (steam, gas), electronics; meters and generators; such a constraint can result among others in high cost of operation, maintenance and in lowered in diffusion of technologies like the Pico/micro/mini hydropower requiring among others importation of pipes.</td>
<td></td>
</tr>
<tr>

1.9 Enabling Framework to Overcome Barriers

Among prioritized technologies for wider development of energy sector in the context of economic growth, poverty reduction and climate change mitigation, some of them are already planned to be implemented mainly before the year 2017. With reference to the updated National Energy Policy and Strategy additional electric power capacity scheduled for installation is about 150 megawatts per year over the period of 2011 to 2017 so that 1052.4 megawatts will be operational in Rwanda as an added capacity in the year 2017 (MININFRA, 2011).

The top prioritized power technologies are geothermal (310 MW), Kivu methane (295.5 MW), hydropower (75.6 MW for small scale and 161MW for large scale) and peat (200MW); being percentage-wise about 29%, 28%, 23% and 19% respectively. In addition to the above main contributing sources, there are two other minor ones: diesel (10MW) and solar photovoltaic (0.3MW).

Our discussion on enabling frameworks for overcoming barriers to transfer and diffusion of energy technologies will be limited, below, to only the five above mentioned prioritized options (geothermal, methane, hydropower, hybrid electric vehicles and solar).

1.10. Cost/benefit analysis

Below we present an analysis of costs and benefits for the five prioritized technologies. We considered the generating costs[ in: US dollars or cents per kWh] of each technology; in fact such a parameter is calculated through an adjusted initial capital cost extended to the overall lifetime, the fixed and variable operation and maintenance costs and, the cost of energy fuels, if any. The benefits [in: kg/MWh or g/kWh] are related to the contribution of energy technologies to the GHG mitigation applications. Therefore we comparatively analyzed the information resulting from the ratio [in: USD/kg or USD/tonnes] between such costs and benefits.

Annual NPV (net present values) have been calculated for each technology over the lifespan for a discount rate of 10% both the costs and benefits have been discounted. Considering the double objective of the TNA project aiming at fighting both “against poverty and against the effects of climate change as interrelated efforts” (UNDP, 2010), the prioritized options include the Kivu methane gas CCGT technology improved by the additional CCS option. In addition to such a double worldwide target, it was suggested by the COP 15 at Copenhagen in December 2009 “to accelerate technology development and transfer in support of action on mitigation that will be guided by a country-driven approach and be based on national circumstances and priorities” (UNFCCC, 2009b). Within the context of the TNA project and with targets mitigating the GHG emissions, below we present an alternative of replacing for instance the oil-fired power technology (gas turbine) by low-carbon technologies.

In fact, about half of total electricity in Rwanda is currently provided by the thermal power plants using imported liquid fuels. From 2005 to 2008, total electricity production was respectively 115.8, 230.4, 248.6 and 276.5 GWh/year. Thus the average increase per year is
40 GWh. Therefore in the coming three years, about 558 GWh, will be required. In case of business-as-usual about 280 GWh will be provided by thermal power plants. The calculations below, i.e tables 24 and 25, are therefore based on the scenario of replacing thermal power plant (280 GWh) by more clean options.

</tbody>
</table>

Given that the CO₂ emission by oil-fired technology is estimated at about 210 000 tons per year, replacement of such a technology by any renewable option will result in a significant mitigation. With regard to the above results, the best scenario is the replacement of oil and diesel-based power technologies by alternatives presenting the lowest amount of CO₂ emission. The indicative cost of environmental externalities is varying between 2 and 28 USD per ton of CO₂ emissions (IPCCC, 2007). Therefore, In consideration of this minimum 2 USD per ton of CO₂ emission; externalities’ costs related to the reduction of GHG emission were agreeable in accordance with the literature related to, among other publications, technical and economic assessment of energy technologies (ESMAP, 2007).
One may wonder how options like geothermal and solar photovoltaic are characterized by an important emission of CO$_2$. This is due to the process of preparation, treatment and other steps in the overall channel network of fuel production. Thus, it is important to remember that such trends are not affecting the operation process during the lifespan of large solar and geothermal plants.

The NPV calculated for each prioritized technology in the sub-sector of electricity and presented above in table 25 proves that all these options are profitable; therefore their diffusion at large scale in Rwanda is recommended (1.10.6 Cost-Benefit Analysis for PHEV)

### Table 26: Operation and maintenance costs of PHEV option

<table>
<thead>
<tr>
<th>Item</th>
<th>Non Efficient fuel vehicle</th>
<th>PHEV</th>
<th>Savings</th>
</tr>

<td>6.8 US cents/km</td>
<td>10.2 US cents/km</td>
</tr>
<tr>
<td>Fuel consumption</td>
<td>2 US cents/km</td>
<td>1.2 US cents/km</td>
<td>0.8 US cents/km</td>
</tr>
<tr>
<td>Operating Cost</td>
<td>0.8 US cents/km</td>
<td>0.7 US cents/km</td>
<td>0.1 US cents/km</td>
</tr>
<tr>
<td>Tires</td>
<td>19.7 US cents/km</td>
<td>8.7 US cents/km</td>
<td>11 US cents/km</td>
</tr>
<tr>
<td>Total</td>
<td>39.5 US cents/km</td>
<td>17.4 US cents/km</td>
<td>22.1 US cents/km</td>
</tr>
</tbody>
</table>

The above data are linked to the following approximate Gasoline fuel cost in Kigali(Rwanda) =1.7 US/liter

Average rate of consumption: 10 liters/100km for conventional vehicle and 4 liters/100km for PHEV

Average mileage distance: 50 km/day i.e. 18250 km/year

Average lifespan = 10 years

The fuel consumption item regards only the fossil gasoline fuel; electricity for recharging the batteries is assumed to come from non carbon fuel

Saving from the use of PHEV instead of pollutant GNEF is 22.1 US cents/km i.e. a rate of reduced operation and maintenance cost of 56%.
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

### Table 27: Reduction of GHG emissions costs

<table>
<thead>
<tr>
<th></th>
<th>Urban circulation</th>
<th>Rural circulation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gasoline non efficient vehicle ((GNEF))</td>
<td>2.3 US cents/km</td>
<td>1.3 US cents/km</td>
</tr>
<tr>
<td>PHEV</td>
<td>0.5 US cents/km</td>
<td>0.47 US cents/km</td>
</tr>
<tr>
<td>Savings</td>
<td>1.8 US cents/km</td>
<td>0.83 US cents/km</td>
</tr>
</tbody>
</table>

The above results are based on an average GHG mitigation cost ranging between 20 and 50 USD per ton of CO\(_2\) equivalent (Litiman, 2012); the CO\(_2\) emission is 458 g/km and 105 g/km respectively for the gasoline non efficient vehicle and the PHEV option in case of urban circulation. Regarding the rural circulation, emissions are 262 g/km and 95 g/km respectively for GNEF and PHEV options.

The above calculation of cost of GHG emission considered the higher rate (50 USD/tone).

Replacement of a GNEF vehicle by a PHEV option results in the savings-related externalities of about 1.8 US cents/km in case of urban circulation. This is justified by the rate of decrease in GHG emission of about 77%. Therefore it is highly recommended to swap from the non efficient cars to cleaner hybrid electric cars. The PHEV technology combined with electricity power generation technologies fully based on non carbon fuels as stated above in the analysis of the four prioritized technologies (geothermal, solar, hydropower and Kivu methane CCGT with optional CCS components); it is expected to play a key role in GHG mitigation in Rwanda.

Finally, for a unit PHEV replacing a conventional non efficient vehicle, the net benefits and savings are about 1693 USD/year in case of an adjusted initial purchase-cost estimated at 4440 USD over a lifespan of 10 years.

### Table 26: Estimated NPV for the PHEV technology

<td>790</td>
<td>718</td>
<td>653</td>
</tr>
</tbody>
</table>

The estimated annual NPV for a PHEV unit is presented above in table 26. They are positive and hence the PHEV technology is profitable. Its potential transfer and diffusion in Rwanda can induce and boost the development of renewable energy use.

*Barrier analysis and enabling framework report*
CHAPTER 2: AGRICULTURE SECTOR

2.1 Preliminary targets for technology transfer and diffusion

2.1.1 Description of targets for prioritized technologies in the agriculture sector
As mentioned in the TNA report, five adaptation technologies were prioritized for the agriculture sector. These include: Seeds and grain storage, Agro forestry, Radical terraces, Drip irrigation and Rainwater harvesting.

2.1.1.1 Targets for seed and grain storage
The target group for the transfer and diffusion of this technology is the farmers’ associations/cooperatives in the first place. These are considered as ideal for the good management and maintenance of the systems once put in place. Although the number of fully operating farmers associations/cooperatives is not yet well known, it is assumed that the entire Rwandan farming community which is estimated at 1 400 000 households will benefit from seed and grain storage technology transfer and diffusion.

The cost of the deployment of the technology is estimated as follow: To install storage capacity of 60 000 tons with modern and well studied drying area, management offices and other supporting equipment it ranges from $ 480000 to $ 900000 in local conditions. This makes the unit cost range from $ 8 to $ 15 / ton. The transfer and diffusion of the technology should start immediately after the TNA project is concluded.

2.1.1.2 Targets for agro forestry
Agro forestry systems being suitable for all kind of farming practices, the target group for its transfer and diffusion is the entire Rwandan farming community. It is estimated that all the sub groups (farming communities, associations and/cooperatives) of the 1 400 000 households involved in farming activities will benefit from agro forestry transfer and diffusion. The average cost to put in place 1 ha of agro forestry plantations is 10 000 $ covering land preparation, seedling preparation (seeds purchasing, tubing, shade construction, nursery maintenance) and baby trees plantation. The transfer and diffusion of the technology should start immediately after the TNA project is concluded.
2.1.1.3 Targets for radical terraces

Radical terraces are ideal for slopes ranging from 13% to 55%, it is estimated that agricultural land with radical terracing potential is owned by 1 000 000 households which are the main part of the Rwandan farming community. For this reason, the transfer and diffusion of radical terracing as an adaptation technology will target 71% of the entire farming community in Rwanda. The average cost to establish one hectare of radical terraces in Rwanda including labor and basic tools such as picks, shovels etc is $1 000 tax exclusive. The cost for any additional unit (ha) of radical terracing would cost the same amount as the initial unit. The transfer and diffusion of the technology should start immediately after the TNA project is concluded.
2.1.1.4 Targets for drip irrigation

The transfer and diffusion of drip irrigation as a technology option for climate change adaption in Rwanda will target farming community populations located in low land regions, the central plateau with no accidental slopes and other areas where the land has been worked so as to be able to cater for agriculture infrastructures. This farming community is estimated at 1,200,000 households which is about 80% of the entire farming community in Rwanda. Looking at the technology diffusion cost, the technology is widely variable; however the cost of a drip irrigation system ranges from US$ 800 to US$ 2,500 per hectare depending on the specific type of technology, automatic devices, used materials as well as the amount of labor required. The transfer and diffusion of the technology should start immediately after the TNA project is concluded.

2.1.1.5 Targets for rainwater harvesting

Rainwater harvesting transfer and diffusion could simply be beneficial to the entire Rwandan population given the country’s relatively high precipitation per annum. In fact, rainfall average is 1400 mm per annum with abundant precipitation of 2000 mm in the North western part of the country and low precipitation of 700 mm in the South eastern part of the country. All the 1,400,000 households which make the Rwandan farming community could benefit from the transfer and diffusion of this technology. The installation of one cubic meter in a small sized (240 m$^3$) runoff pond system costs $15. The cost to install one cubic meter in rooftop rainwater harvesting system varies depending on the tank type:

1. With plastic tank: $230
2. Stone and concrete tank: $220

The transfer and diffusion of the technology should start immediately after the TNA project is concluded.

2.1.2 Methodology

In the first place, literature review was carried out by the consultant in order to list and classify barriers that may hinder the transfer and diffusion of prioritized technologies for the agriculture sector based on guidelines as elaborated and published by the UNDP. Initially, barriers hindering transfer and diffusion of prioritized technologies in the agriculture sector were classified into four main categories: technological, financial, economic and institutional. Being barriers or measures, two types are considered in the context of speed of diffusion;
financial and non financial. Thus for measures we can simplify and consider only two types: financial and non financial measures. Our methodology also considered a consultation process during which listed barriers were discussed among a wide scope of stakeholders including agriculture and finance experts, academics, researchers, NGOs representatives and the media. The consultation was initiated by individual meetings to draft relevant suggestions, and concluded by a workshop where the outcome of individual meetings was discussed and finalized. The workshop was held on 4th September 2012 at Umubano Hotel, Kigali, Rwanda.

2.2 Barrier analysis and possible enabling measures for agro forestry

2.2.1 General description of agro forestry

Agro-forestry is an integrated approach to the production of trees and of non-tree crops or animals on the same piece of land. The crops can be grown together at the same time, in rotation, or in separate plots when materials from one are used to benefit another. Agro-forestry systems take advantage of trees for many uses such as: to hold the soil, to increase fertility through nitrogen fixation, or through bringing minerals from deep in the soil and depositing them by leaf-fall; and to provide shade, construction materials, foods and fuel (climatetechwiki.org).

2.2.2 Identification of barriers for agro forestry

Rwandan agriculture is one of the sectors which are vulnerable to the effects of climate change especially soil erosion as a result of heavy rains. The country holds a total space of 1.4 million hectares with agricultural production potential. The same space can be used for agro forestry development which would help the agriculture sector and the country in general to adapt to the effects of climate change. However, there exist barriers that hinder proper implementation of the technology in Rwanda. The following key barriers have been identified:

1. Agro forestry inputs are not well distributed which makes them not easily accessible to local farmers. These include: seeds, germplasm and credit.

2. Lack of demonstration plots: Farmers are difficult to convince unless they see the advantages of agro forestry. Very few demonstration plots have been established as case studies to generate concrete results.
3. There exists gaps of knowledge on agro forestry systems among agriculture extension agents who are in regular contact with farmers.

4. Farmers are not prepared to invest in agro forestry for long term benefits. They prefer immediate benefits

5. There is also lack of infrastructure for handling and processing of existing agro forestry products and lack of marketing services.

2.2.3 Proposed measures to overcome barriers for agro forestry

With respect to barriers translated into causes and effects of not fully adopting agro forestry as an adaptation technology option to climate change in Rwanda, identified measures to overcome the barriers are presented in table 28. Mainly, technical knowledge gaps which exist in the agro forestry industry can be dealt with through training, information sharing workshops and study tours. The legal framework should also be elaborated in order to adapt it to current country needs and priorities.

2.2.4 Enabling framework

Through its Strategic Plan for the Transformation of Agriculture (PSTA II), Rwanda has set up several mechanisms that would enable the implementation of technologies which improve agricultural production while sustaining the environment. Different government institutions/agencies have been given different mandates and roles which provide an ideal framework for technology transfer and diffusion among the population. For example ministries are policy makers while government agencies together with local government entities are policy implementers.

Based on the proposed measures, the table below illustrates enabling environment that complements the existing institutional framework in order to overcome identified barriers that may hamper the development of agro forestry in Rwanda.

2.2.5 Cost benefits analysis for agro forestry

**Measures**

The key barrier to transfer and diffusion of agro forestry is limited adoption of agro forestry systems among farmers.

The target when transferring and diffusing this technology would be to make agro forestry systems fully adoptable within farming communities.

List of alternative measures:

Know how, rural policies, awareness raising, access, subsidies etc

Complimentary measures:

a) Improvement of existing technical knowledge

b) Revision of agro forestry legal framework

c) Creation of awareness among farmers

d) Promote access to credit and reduce interest rates

e) Reduction of charges to farmers on initial investment on agro forestry development through subsidies on inputs (seedlings and fertilizers)

**Costs**

1. Awareness and knowledge raising among farmers
   Cost of trainers, workshops and training material

   In the first year, a starter pack would be made available and be distributed to each of the farming households to allow farmers learn about the benefits of agro forestry.

   The cost of a representative pack was estimated at $15 per household including training and information.

   The total cost was estimated at: $15*1 400 000 households= $ 21 million

2. Subsidies to cover a share of costs on initial investment

   Assuming that each household will be 100% provided with seedlings to be planted on 0.01 ha (10 seedlings) at an average cost of $ 0.1 per seedling, the total cost would be:  $ 0.1*10*1 400 000= $ 1.4 million

3. Ensure access to available inputs such as seedlings and fertilizers

   Costs related to legal reforms and infrastructure

   We assumed this to be part of the overall development agenda and we did not estimate any cost.

Other cost:
These would include labor, land and fertilizers. Regarding labor this is only man power since Rwandan agriculture is human labor intensive. The agriculture land generally belongs to the farmer and in most cases it is inherited from the family. We also assume that most the fertilizers to be used will be organic manure available locally at a negligible cost.

Total costs: (awareness and knowledge raising + subsidies on initial investments cost + related to legal reforms and infrastructure + other costs)

Total costs (USD) year 1: 21 million + 1.4 million + 0 + 0
= 22.4 million

Total costs (USD) year 2: 0 + 1.4 million + 0 + 0
= 1.4 million

Benefits:
Starting in Year 5, one-fourth of the trees will be coppiced annually and sold as building poles for $0.40 each.

Assuming that fruit trees will be 50% of the total planted trees and the total number being 14 million per annum, sales of buildings will be:

$0.40 * ¼ (7 million) = $0.7 million from year 5

Starting in Year 7, $5 worth of fruit will be sold each year.

Fruit sales will be:

5$ * 7 million tree = $35 million from year 7

The discount rate was fixed at 5% and 9%

By Year 10, crops yields (i.e. maize) and revenues on the remaining land will be 22% higher than they would have been without the trees. (Costs of planting and harvesting the maize remain constant.) This assumes an absolute increase in yields of 11% over ten years, compared with a decrease of 11% if the trees had not been planted.
2.3 Barrier analysis and possible enabling measures for drip irrigation

2.3.1 General description of drip irrigation

Drip irrigation is a technology based on the constant application of a specific and focused quantity of water to soil crops. The system uses pipes, valves and small drippers or emitters transporting water from the sources (i.e. wells, tanks and or reservoirs) to the route area and applying it under particular quantity and pressure specifications. Compared to surface irrigation, which can provide 60 per cent, water-use efficiency and sprinklers systems which can provide 75 per cent efficiency, drip irrigation can provide as much as 90 per cent water-use efficiency (FAO, 2002).

2.3.2 Identification of barriers for drip irrigation

The majority of Rwandan farmers (about 90%) still rely on rain fed agriculture which makes agriculture production much more vulnerable to irregular rainfall and prolonged draughts. With an estimation of 589 000 ha of potential irrigable land, the government of Rwanda through the Ministry of Agriculture has targeted to irrigate at total space of 100 000 ha by 2017 from 18 000 ha in 2011 mostly using flood irrigation which, combined with unreliable precipitation will put more pressure on water resources.

Drip irrigation has been identified as the most efficient technology to assist the agriculture sector/production to adapt to the effect of climate change, especially by reducing water consumption given its 90% efficiency on water use. In local context, barriers to the implementation of the technology have been identified as follows:
Table 31: Identified barriers that may hamper the implementation of drip irrigation in Rwanda

<td>Important</td>
</tr>
</tbody>
</table>
Table 3 below highlights measures which would assist to overcome identified barriers in implementing drip irrigation. Local importers and manufacturers would be convinced to import and manufacture drip irrigation equipment by offering them loans at reduced interest rates and through tax exemptions on raw materials. Through subsidies, charges to farmers on initial investment of drip irrigation systems purchase and installation can be reduced making drip irrigation systems more affordable. Decentralizing agriculture development funds up to sector level would facilitate farmers’ to access funds. Technical skills on drip irrigation can be developed through training, workshops and study tours. Local agriculture practitioners should be educated about the vital role of water in plant growth and productivity by comparing well irrigated crops/fields against non-irrigated crops/fields using demonstration fields.

</tbody>
</table>
-Organize seminars  
-Conduct workshops  
-Organize and conduct study trips on drip irrigation

Educate local agriculture practitioners about the vital role of water in plant growth and productivity:  
-Organize training of trainers through workshops, seminars, show casing, demonstration plots.  
-Conduct farmers awareness campaign by using awareness materials, the media like news papers (Imvaho nshya), Radio (Rwanda, Contact fm, Flash fm, Salus fm and others)

2.3.5 Cost benefit analysis for drip irrigation

**Measures**

The key barrier to transfer and diffusion of drip irrigation is limited acceptance of drip irrigation systems.

The target when transferring and diffusing this technology is increased acceptance of drip irrigation.

List of alternative measures:

Access to loans, tax exemption, subsidies, know-how, awareness raising

Complimentary measures:

a. Create interest among local importers through improved access to loans at reduced interest rates.

b. Create interest among local manufacturers by guaranteeing tax exemption on raw material
   - Reduce charges to farmers on initial investment of drip irrigation installations through subsidies.
   - Improve existing technical skills on drip irrigation through training, workshops and study tours
e. Educate local agricultural practitioners about the vital role of water in plant
growth and productivity through awareness campaigns.

**Costs**

1. The creation of interest among local importers through improved access to loans at reduced interest rates.

We assume that this programme is included in current planned financial reforms and do not estimate any cost.

2. The creation of interest among local manufactures by guaranteeing tax exemption on raw material.

No cost is estimated since tax exemption on raw material is one of the mechanisms which the government of Rwanda adopted in order to promote the development of the manufacturing sector.

3. Subsidies to cover a share of costs on initial investment.

Assuming that each of the 1.2 million farming households which would directly benefit from drip irrigation transfer and diffusion will be assisted at 50% in order to acquire a drip irrigation system able to water 0.04 ha each year at a cost of $1650 per hectare, The total cost would be:  
\[
[50 \% \times (\$1650 \times 0.04) \times 1 \text{2}00 \text{000}] = \$39 \text{ million}
\]

4. Improve existing technical skills on drip irrigation through training, workshops and study tours

At the beginning of the programme a starter pack would be made available and be distributed to each of the benefiting households (1.2 million) to allow the community familiarize themselves with the technology.

The cost of the starter pack was estimated at $15 per household including training and information.

The total cost for capacity building is estimated at:  
\[
\$15 \times 1 \text{2}00 \text{000} \text{ households} = \$18 \text{ million}
\]

Other cost:

These would include system maintenance and other irrigation infrastructures which are estimated at $100 per hectare per year.  
\[
(\$0.04 \times 100) \times 1200000 \text{ households} = \$4.8 \text{ million}
\]

Total costs: (improved access to loans + tax exemption + subsidies on initial investment + technical skills + other costs)

Total costs (USD) year 1:  
\[
0 + 0 + 39 \text{ million} + 18 \text{ million} + 4.8 \text{ million}
\]

= 61.8 million

Total costs (USD) year 2:  
\[
0 + 0 + 39 \text{ million} + 0 + 4.8 \text{ million}
\]
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

= 43.8 million
Benefits:
In the first place, the adoption of drip irrigation would allow farmers to harvest four times a year instead of two.
Assuming that corn is produced all over the country with average yields of 5 tonnes per hectare at a price of $60 per ton, it comes to $300 of sales of corn per hectare.
Net benefit is estimated at: (sales-inputs and labor)

\[ \text{Net benefit} = \text{sales} - \text{inputs and labor} = 300 - 225 = 75 \text{ per hectare} \]

Total benefit is: \( (75 \times 0.04 \times 1200000 \text{ households} \times 2) = 7 \text{ 200 000 per annum} \)

</tbody>
</table>

As an adaptation technology option, the key benefits of drip irrigation system are as follows:
- It is a convenient and efficient way to supply water directly into the soil along individual crop rows and surrounding individual plant roots.
- It saves money by using water and labor efficiently.
- It can effectively deliver very small amounts of water daily, which can save energy; increase yields and minimize leaching of soluble chemicals.

2.4 Barrier analysis and possible enabling measures for rain water harvesting

2.4.1 General description of rain water harvesting

Rain water harvesting is a technology used for collecting and storing rainwater from rooftops, the land surface or rock catchments using simple techniques such as jars and pots as well as more complex techniques such as underground check dams. Commonly used systems are constructed of three principal components; namely, the catchment area, the collection device, and the conveyance system.

2.4.2 Identification of barriers for rain water harvesting

In Rwanda, most pressure in agricultural water use comes from the continuously increasing irrigated space and this depends on how efficiently water is used. As rainfall becomes unreliable and extreme water conditions intensify, it is becoming a must to expand
agricultural irrigated land using harvested rainwater as a water source and using all water harvesting methods which include: runoff ponds, pitting methods, trenching methods etc. Through technology needs assessment, barriers that may hamper the implementation of rainwater harvesting as a climate change adaptation option have been identified as shown in the table below.

**Table 35: Identified barriers that may hamper the implementation of rainwater harvesting in Rwanda**

2.4.5 Cost benefit analysis for rainwater harvesting

Measures

The key barrier to transfer and diffusion of rainwater harvesting is limited adoption of rainwater harvesting systems among rural communities. The target when transferring and diffusing this technology is rainwater harvesting systems adoption within rural communities.

List of alternative measures:

Subsidies, access to loans and know-how.

Complimentary measures:

a. Reduce charges to farmers on the cost of rainwater harvesting systems through subsidies
b. Facilitate farmers to access funds by decentralizing agriculture development funds up to sector level
c. Improve technical skills and know how on rainwater harvesting techniques through trainings, workshops and study tours

Costs

1. Subsidies to cover a share of cost on initial investment

It was established that all the 1.4 million households involved in farming activities would benefit from rainwater harvesting. Taking the cost of one cubic meter rooftop rain water collection and storage at $220 as a baseline and subsidies are fixed at 50% of the cost a rainwater harvesting system with a capacity of one cubic meter per household;

Subsidies are estimated as follow:

\[50\% \times (220 \times 0.1) \times 1400000 \text{ households}\]

\[= \$15,400,000 \text{ per annum}\]

2. The facilitation of farmers to access funds/loans

This component appears on the country’s development programmes, therefore no cost is estimated

3. Improvement of technical skills and know-how on rainwater harvesting techniques.

We assume that two people per sector will be trained in order to provide needed technical assistance to the farmers. The number of administrative sectors is 418 and the cost to train one person is estimated at $2000.
Total capacity building costs are estimated as follow:

\[ 2000 \times 2 \times 418 \]
\[ = 1,672,000 \]

Other costs: These are related to system maintenance and renovation and are estimated at 5$ installed cubic meter per annum which is 
\[ 5 \times 1,400,000 = 7,000,000 \]

Total costs: (subsidies on initial investment + improved access to loans + technical skills +
other costs)

Total costs (USD) year 1: 
\[ 15,400,000 + 0 + 1,672,000 + 7,000,000 \]
\[ = 24,172,000 \]

Total costs (USD) year 2: 
\[ 15,400,000 + 0 + 0 + 7,000,000 \]
\[ = 22,400,000 \]

Benefits

Harvesting rain waters especially for agricultural purposes would allow farmers to harvest four times a year instead of two.

Assuming that corn is produced all over the country with average yields of 5 tonnes per hectare at a price of $60 per ton which is $300 of sales of corn per hectare.

Net benefit is estimated at: (sales-inputs and labor)

\[ \$300 - 225 = \$75 \text{ per hectare} \]

Total benefit is: 
\[ (\$75 \times 0.04 \text{ ha of irrigated fields per annum} \times 1,400,000 \text{ households} \times 2 \text{ additional harvests}) \]
\[ = \$8,400,000 \text{ per annum} \]

</table>

Other benefits qualified as qualitative/adaptative include; but not limited to:
- High soil erosion reduction potential
- High flooding reduction potential
2.5 Barrier analysis and possible enabling measures for radical terraces

2.5.1 General description of radical terraces

Radical terracing refers to a technique of landscaping a piece of sloped land into a series of successively receding flat surfaces or platforms, which resemble steps, for the purposes of more effective farming. This type of landscaping, therefore, is called terracing. Graduated terrace steps are commonly used to farm on hilly or mountainous terrain. Terraced fields decrease erosion and surface runoff retaining soil nutrients.

According to Mupenzi et al. 2012, radical terraces contributed to increase in the farm productivity, fight against erosion and also contributed to poverty reduction in Rwanda.

2.5.2 Identification of barriers for radical terraces

Radical terraces have been selected as one of the technologies that are most suitable in assisting the agriculture sector and Rwanda in general to adapt better to the adverse effects of climate change. The selection was due to their benefits which include: a) Enabling the development of larger areas of arable land in rugged terrain; b) Facilitating modern cropping techniques such as mechanization, irrigation and transportation on sloping land, c) Increasing the moisture content of the soil by retaining a larger quantity of water, d) Capturing run-off soil which can be diverted through irrigation channels at a controlled speed to prevent soil erosion and others. However, there exists barriers which may hamper their proper implementation in Rwanda as identified in the table below.
Table 39: Identified barriers that may hamper the implementation of radical terraces in Rwanda

2.5.5 Cost benefits analysis for radical terraces

**Measures**

The key barrier to transfer and diffusion of radical terraces is limited adoption of radical terraces among rural communities.

The target when transferring and diffusing this technology is radical terraces adoption within rural communities.

List of alternative measures:

- Incentives, know how, baseline surveys, awareness campaigns.

Complimentary measures:

- a. Reduce the cost of needed terracing tools through the provision of incentives to local manufacturers.
- b. Conduct training for skills and know how improvement.
- c. Conduct surveys in order to have a baseline on which countrywide terracing would be based.
- d. Conduct awareness campaigns on the long term benefits of radical terraces.
- e. Provision of incentives to local manufacturers to reduce the price of basic terracing tools.

**Costs**

1. It was established that a total of 294 000 ha of arable land needs the establishment of radical terraces.

The cost to establish 1 ha of radical terraces is estimated at $1 000. The cost of tools (shovels, tridents, etc.) is 40% of the total cost which is $400 per hectare. Assuming that manufacturers are provided with incentives totaling 50%, total incentives are estimated as follow:

\[
\text{[50\% (400 * 294 000)/10]}
\]

\[= $ 5 800 000 \text{ per annum}\]

2. Conduct training for skills and know how improvement.

Assuming that a representative starter pack will be given to each of the benefiting households at the beginning of the programme at a cost of $17 per household including the cost of establishing demonstration plots,

The total cost for capacity building is estimated at:

\[\$20*1 000 000 = $ 20 000 000\]
3. Conducting baseline surveys at a cost of $200 per hectare
   Total cost for baseline surveys are estimated as follow:
   \((\$200 \times 294,000) / 10 = \$5,800,000\) per annum

4. Conduct awareness campaigns
   This cost is not given a numerical value as we assumed that it will be integrated into other agro extension activities
   Other costs include labor + other inputs
   \(= [\$200 \times 294,000] + [20 \times 294,000] / 10\)
   \(= \$6,321,000\) per annum

Total cost: (incentives to local manufacturers + capacity building through trainings + conduct baseline surveys + cost of awareness campaigns + other costs including labor and other inputs)

Total costs (USD) year 1: \(\$5,800,000 + \$20,000,000 + \$5,800,000 + 0 + \$6,321,000\)
   \(= \$37,921,000\)

Total costs (USD) year 2: \(\$5,800,000 + 0 + \$5,800,000 + 0 + \$6,321,000\)
   \(= \$17,921,600\)

**Benefits**

Adequate radical terracing results in increment of yield up to 10% for corn and 10% increment of productive space mainly used for agro forestry and forage.

Assuming that all the installed radical terraces are used to produce corn, which gives yields of 5 tonnes per hectare in normal conditions, financial benefits are estimated as follow:

1. Benefits resulting from normal corn yields + increase in yields as a result of radical terraces:

   From year 3 there will be:

   Sales of normal yields (in the absence of radical terraces)
   \([\$60 \times 294,000] / 10 = \$1,764,000\) per annum

   Sales of 10% increase in yields as a result of radical terracing
   \([10\% \times (\$60 \times 294,000 \text{ ha} \times 5 \text{ tonnes})] / 10\)
   \(= \$882,000\) per annum

2. Benefits resulting from increase in productive space:
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

Assuming that the 10% additional space is used for agro forestry trees at a rate of 1000 trees per hectare with 50% of the trees being fruits trees, benefits are estimated as follow:

From year five, one-fourth of the 50% of all the trees will be coppiced annually and sold as building poles for $ 0.40 each.

\[\$ 0.40 \times \left[\frac{50\% \times (294000 \text{ ha} \times 1000)}{4}\right]/10 = \$ 1 470 000 \text{ per annum}\]

It is assumed that main agro forestry inputs such as seedlings are fully subsidized

Starting in Year 7, $5 worth of fruit will be sold each year.

\[\$ 5 \times \left[50\% \times (294000 \text{ ha} \times 1000)\right]/10 = \$ 73 500 000 \text{ per annum}\]

Other adaptation benefits include:

- Soil erosion reduction potential
- Water conservation
- Natural hazards (land slide) minimization.
2.6 Barrier analysis and possible enabling measures for seed and grain storage

2.6.1 General description of seed and grain storage

Good seed and grain storage helps ensure household and community food security until the next harvest. Commodities for sale can be held back so that farmers can avoid being forced to sell at low prices during the drop in demand that often follows a harvest. While considerable losses can occur in the field, both before and during harvest, the greatest losses usually occur during storage. Therefore the basic objective of good storage is to create environmental conditions that protect the product and maintain its quality and its quantity, thus reducing product loss and financial loss. Only well-dried seeds should be stored. Seeds with moisture in them become damp, moldy and vulnerable to insect attacks.

2.6.2 Identification of barriers for seed and grain storage

Rwanda has established a National Post-Harvest Staple Crop Strategy which is a policy framework to assist with strengthening the harvesting, post-harvest handling, trade, storage, and marketing within staple crop value chains. All these are meant to help strengthening markets and linkages for farmers, and reducing post-harvest losses which would compromise food security.

Adequate seed and grain storage being critical in food security, the technology intervenes as one of the techniques used in post harvest and has been selected as one of the technologies that would assist the country in fighting adverse effects of climate change. However, there exist barriers that may hamper the implementation of the technology as presented in the table below.
Table 43: Identified barriers that may hamper the implementation of seed and grain storage in Rwanda

2.6.5 Cost benefits analysis for seed and grain storage

**Measures**

The key barrier to transfer and diffusion of radical terraces is limited acceptability of seed and grain storage within rural communities.

The target when transferring and diffusing this technology is seed and grain storage systems acceptance within rural communities.

List of alternative measures:

Incentives, subsidies, rural infrastructures, know how

Complimentary measures:

- Reduce initial investment costs through incentives and subsidies
- Improvement of basic rural infrastructures through construction of new rural feeder roads and improvement of existing ones
- Provide technical skills in installation and maintenance of seed and grain storage systems by organizing/conducting seminars, workshops and showcasing through demonstration plots and study tours
- Provision of incentives to local manufacturers and importers in order to make available needed components

**Costs**

1. The cost establishing an efficient seed and grain storage of one metric tonne in a 60 000 metric tonnes capacity system is $15.

Total incentives at 50% rate are estimated at:

\[
\frac{0.5 \times (15 \times 400000)}{10} = 300000 \text{ per annum}
\]

Subsidies are estimated at:

\[
\frac{0.5 \times (15 \times 400000)}{10} = 300000 \text{ per annum}
\]

2. The cost of improving rural infrastructures is assumed to be covered under other development programmes and no cost estimates are established.

3. Conduct trainings for skills and know how improvement

We assume that two people per sector will be trained in order to provide needed technical assistance to the farmers. The number of administrative sectors is 418 and the cost to train one person is estimated at $2000.

Total capacity building costs are estimated as follow:
2000*2*418
= $1,672,000

Other costs are related to system maintenance which is estimated at 10% of the total cost of the installation of one metric tonne

= [10%*(400,000*15)]/10
=$60,000 per annum

Total cost: (incentives to local manufacturers + subsidies to farmers + infrastructure + capacity building through trainings + other costs which are mainly maintenance costs)

Total costs (USD) year 1: $300,000 + $300,000 + 0 + $1,672,000 + $60,000
= $2,320,000

Total costs (USD) year 2: $300,000 + $300,000 + 0 + 0 + $60,000
= $660,000

Benefits
Direct benefits are those related to reduction of post harvest losses. In fact adequate seed and grain storage systems allow farmers to save 60% yields under storage.

Assuming that only corn grains are stored. Direct benefits are estimated as follow:

[60% ($60*400,000)]/10
=$1,440,000 per annum

</tbody>
</table>

The adaptation benefit of adequate seed and grain storage relies in its capacity to ensure food security and availability of quality seeds in case of bad harvests.
2.7 Linkages of barriers identified for the agriculture sector

During barrier analysis exercise, linkages between technologies were identified. The most common barrier for all the five technologies prioritized for the agriculture sector is gaps and/or lack of technical skills and knowledge. High cost of technology implementation has also been identified as a cross cutting barrier for all the technologies. Other barriers include: Difficult access to funds, lack of awareness about the benefits of the technologies and limited rural infrastructures.

Complementarities have also been established between all the five prioritized technologies. In fact, a good agro forestry system would be supported by the establishment of radical terraces for possible extension, especially in the Rwandan context where land size is a crucial problem in agriculture production. On the other hand, radical terraces would benefit from agro forestry systems in the sense that they contribute to soil fertility improvement through biomass (leaves) fall and decomposition, therefore increasing their productivity. Agro forestry species also contribute to radical terraces slope protection. Given the general slope of Rwandan agriculture land (13%-55%) and its related impacts such as increased runoff leading to soil erosion and land slide, rainwater harvesting and drip irrigation should be done after radical terraces and agro forestry systems are in place so as to maximize system outputs. Seed and grain storage is here considered most needed once the used of the other four technologies is optimized.

Annexes

Annex 1- Market maps, problem and solution trees

1.1 Energy sector

1.1.1 Problem trees
Large Solar PV Technology

Increased GHG emission → Limitations in new investments → Limited growth of industry → Large use of wood fuels and important deforestation

Increased Use of fossil fuels for power generation → Bill of energy is very high → Low rate of access to electricity → Very low benefit from solar resources

Very high initial capital cost

Inexistent local manufacture/ solar industry → High transaction cost → High cost of equipments and maintenance

Limited info on grid connected solar → Unfamiliarity with private mini grid → Solar products are at high import duties → Limited access to loans; high interest rates

Weak awareness for solar → Limited human skills in solar opportunities → Limited involvement in research and solar studies → Low market competitiveness and returns

Limited involvement in research and solar studies → Low market competitiveness and returns → Non operational Carbon credit market

Insufficient incentives and subsidies

Insufficient incentives and subsidies → Limited involvement in research and solar studies → Weak awareness for solar

Limited involvement in research and solar studies → Limited human skills in solar opportunities → Unfamiliarity with private mini grid

Limited info on grid connected solar → Inexistent local manufacture/ solar industry

Very high initial capital cost

Feed-in-tariff (FIT): inexistent → Expensive transformation of raw materials into solar PV → Long process of verification by the CDM program

FIT factors are not well understood policy makers → Low market competitiveness and returns → Limited access to loans; high interest rates

Limited access to loans; high interest rates → High cost of equipments and maintenance

High transaction cost

Inexistent local manufacture/ solar industry

Very high initial capital cost

Large use of wood fuels and important deforestation → Very low benefit from solar resources → Limited growth of industry → Limitations in new investments → Increased GHG emission

Increased Use of fossil fuels for power generation
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

**Small Hydropower**

- High pressure on forests and land vegetation cover
- Overloaded EWSA in modern energy sector
- Use of traditional biomass for energy supply at large scale in rural areas
- Public EWSA almost alone in developing hydropower at different scales
- Limited growth of small scale industry in Rwanda
- Low level of electrification in rural areas
- A lot of potential sites for hydropower (Pico, micro) not exploited

**Limited involvement of private developers**

- Low financial capacity of private sector
- High cost of equipments
- High cost of construction and installation
- Low access to loans
- Insufficient Skilled expertise and workers
- A heavy guaranty (as key condition for loans) is requested by banks
- All equipments are imported
- Limited training in hydropower and related areas
- Inexistent local manufacture
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

**Kivu Methane CCGT**

- Large use of wood fuels in industry and households
- Exploitation of Kivu methane still only pilot project
- Oil for electrification generation still in use
- Limitation in electricity generation
- GDP still limited
- Economic growth suffering from insufficient energy

**High cost of methane production**

- High cost of liquefied methane’s distribution to consumers
- Targeted consumers are not only near the methane stations
- Limited sources of thermal energy to industries and households
- High cost for management of H₂S separated from the extracted mixture of gases
- H₂S is not yet used in local industry
- Limited awareness about the production of sulfuric acid
- High cost of reinjection of CO₂ (separated from mixture) into the lake
- Studies on CO₂ demand and use by industry are not done
- Low knowledge and awareness about opportunities CO₂
- Important distance to the electric grid
- EWSA grid: not available near all future methane stations
- Grid extension is not planned along the Lake Kivu belt

Barrier analysis and enabling framework report
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

**Geothermal**

- Bill of petroleum fossil fuels is high
- Weak increase in GDP
  - Limited speed of economic growth
  - Contribution to jobs’ creation is missing
- High dependence to oil for power generation
- Contribution to jobs’ creation is missing
- Rate of electrification is still low
- Impossible benefit from carbon credits market
- Geothermal remains unexploited
- Unknown potentialities in geothermal resource

- High cost of exploration and investigation
- Limited research undertaken for resources in Rift Valley branch
- Expected pilot project in northern region of country is not yet installed
- High cost of drilling and managing the well holes for observation
- Insufficient number of skilled human personnel

- Location, depth and size of underground reservoirs are unknown
- Limited funds for training in such a multidisciplinary area of geothermal
- Very high cost of equipments
  - Facilities from partners not made available
  - Low awareness in underground natural resources
  - Resistance to new technologies
  - Public financial limitations
  - Limited funds for training in such a multidisciplinary area of geothermal
  - Public financial limitations
  - Limited funds for training in such a multidisciplinary area of geothermal
  - Public financial limitations
  - Limited funds for training in such a multidisciplinary area of geothermal
  - Public financial limitations
  - Limited funds for training in such a multidisciplinary area of geothermal

*Barrier analysis and enabling framework report*
**PHEV**

- Fossil Energy Bill progressively increase
- Related jobs are not created
- GHG emissions due to transport are increased
- Increasing the importation of gasoline and diesel
- Local industry of Transport and manufacturing units are not promoted
- Number of convention vehicles is regularly increasing

**Very low demand of PHEV**

- Predominance of conventional gasoline and diesel vehicles
- High purchase cost of PHEV
- Unfamiliar type of vehicles

- Important market of second-hand vehicles
- Conventional vehicles are largely affordable
- Inexistent incentives for deployment of PHEV
- Inexistent pre-conditions i.e. industry of batteries and electric motors
- Hesitating private promoters for such new vehicles
- Insignificants campaigns for cleaner vehicles

- New vehicles are very expensive
- Environment externalities are not included into costs
- Limited information about role of promoting PHEV
- Very limited investment in local electronics and chemical
- Non-access to loans and to subsidies for PHEV
- Insufficient awareness about the PHEV applicability

- Low awareness about pollution by vehicles
1.1.2 Solution trees

**Large Solar PV Technology**

- **Reduced GHG emission**
- **Increase in new investments**
- **Sufficient growth of industry**
- **Decreasing use of wood fuels and lowered deforestation**

- **Decreased use of fossil fuels for power generation**
- **Bill of energy is acceptable**
- **High rate of access to electricity**
- **Significant benefit from solar resources**

**Affordable initial capital cost**

- **Local manufacture/ solar industry is operational**
- **Acceptable transaction cost**
- **Affordable cost of equipments and maintenance**

- **Flowing info on grid connected solar**
- **Installation of private mini grid**
- **Solar products are at low import duties**
- **Significant access to loans and acceptable interest rate**
- **Affordable cost of raw materials into solar PV**

- **Enhanced awareness for solar**
- **Enhanced human skills in solar opportunities**
- **Tangible involvement in research and solar studies**
- **Reasonable market competitiveness and returns**
- **Carbon credits market are operational**

- **Feed-in-Tariff (FIT) is applied**
- **Affordable transformation of raw materials into solar PV**
- **Accelerated process of verification by CDM**

---

8 Banks can play a key role in placing a given technology on a competitive and sustainable footing (Sirnivasson, 2009); Cash-payment market is replaced by credit-payment market
Small hydro power

Rapid growth of small scale industry in Rwanda

High level of electrification in rural areas

A lot of potential sites for hydropower (pico, micro) became exploited

Important involvement of private developers

Sufficient financial capacity of private sector

Large access to loans

An acceptable guaranty (as key condition for loans) is requested by banks

Affordable cost of equipments

Only some specific equipment is imported

Established local manufacture

Acceptable cost of construction and installation

Sufficient Skilled expertise and workers

Significant training in hydropower and related areas

Weak pressure on forests and land vegetation cover

Use of traditional biomass for energy supply at lower scale in rural areas

Shared involvement with EWSA in modern energy sector

Public EWSA not alone in developing hydropower at different scales

Barrier analysis and enabling framework report
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

**Kivu Methane CCGT**

- Decreased use of wood fuels in industry and households
- Exploitation of Kivu methane now beyond pilot project
- Oil for electrification generation minimized
- Wider capacity in electricity generation
- GDP has reached a medium level
- Economic growth benefiting from sufficient energy supply

**Affordable cost of methane production**

- Decreased cost of liquefied methane’s distribution to consumers
- Targeted consumers are only near the methane stations
- Thermal alternatives for industries and households are made available
- Lowered cost for management of H₂S separated from the extracted mixture of gases
- H₂S is largely used in local industry
- Increased awareness about the production of sulfuric acid
- Reduced cost of reinjection of CO₂ (separated from mixture) into the lake
- Studies on CO₂ demand and use by industry are made available and applied
- Enhanced knowledge and awareness about opportunities CO₂
- Reduced distance to the electric grid
- EWSA grid: made available near all future methane stations
- Grid extension is done along the Lake Kivu belt

Barrier analysis and enabling framework report
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

**Geothermal**

- Bill of petroleum fossil fuels is minimized
- Very low dependence to oil for power generation
- Geothermal is largely exploited
- Identified potentialities in geothermal resource
- Affordable cost of exploration and investigation
- Location, depth and size of underground reservoirs are known
- Supported research undertaken for resources in Rift Valley branch
- Sufficient number of skilled human personnel
- Sufficient funds for training in such a multidisciplinary area of geothermal
- Enhanced awareness in underground natural resources
- Sufficient increase in GDP
- Acceptable speed of economic growth
- Rate of electrification is high
- Possible benefit from carbon credits market
- Public financial capacity is acceptable
- Facilities from partners are made available
- Acceptability and support of new technologies
- Expected pilot project in northern region of country is now installed
- Adjusted and lowered cost of drilling and managing the well holes for observation
- Affordable cost of equipments
- Affordability of cost of equipments
- Acceptability of cost of equipments
- Acceptability of cost of equipments
**PHEV**

- Fossil Energy Bill progressively reduced
- Related jobs are largely created
- GHG emissions due to transport are largely reduced
- Decreasing the importation of gasoline and diesel
- Local industry of Transport and manufacturing units are progressively promoted
- Number of convention vehicles is regularly decreasing
- Reasonable demand of PHEV
- Weakened market of conventional gasoline and diesel vehicles
- Affordable purchase cost of PHEV
- Popularized type of vehicles
- Reduced market of second-hand vehicles
- Conventional vehicles are largely expensive
- Sufficient incentives for deployment of PHEV
- Established pre-conditions i.e. industry of batteries and electric motors
- Active private promoters for such new vehicles
- Fruitful campaigns for cleaner vehicles
- New vehicles are affordable
- Environment externalities are fully included into costs
- Flowing information about role of promoting PHEV
- Reasonable investment in local electronics and chemical
- Large access to loans and to subsidies for PHEV
- Acceptable awareness about the PHEV applicability
- Low awareness about pollution by vehicles
1.2 Agriculture sector

1.2.1 Market maps

Seed and grain storage
Drip irrigation

**Enabling environment**
- Tax exemption on imported drip irrigation components
- Subsidies on loan interest
- Clear irrigation policy and strategy
- Irrigation standards
- Corruption control

**Market chain actors**
- Large scale drip irrigation systems
- Medium scale drip irrigation systems
- Small scale drip irrigation systems
- Drip irrigation systems operators
- DI main components retailers
- DI support services providers
- DI main components importers
- DI accessories importers
- DI maintenance services providers

**Service providers**
- Information campaigns
- Financial services
- Education and training
- Insurance
Rainwater harvesting
1.2.2 Problem and solution trees

Seed and grain storage

Problem tree

Reduced income and food security

Decrease in yields

Persistent use of low quality seeds

Limited acceptability of Seed and grain storage systems within communities

Lack of technical skills in installation and maintenance of seed and grain storage systems

Absence of specific training on installation and maintenance of seed and grain storage systems

Absence of adequate technical training schemes

Delays in components deliveries

Most of the material is imported

Absence of Local manufacturers

Absence of incentives

High initial investment cost

Expensive material/components

Limited rural infrastructures such as farm access roads

No development of rural feeder and farm access roads

Lack of rural feeder and farm access roads mechanisms
Solution tree

Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

Barrier analysis and enabling framework report

118
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

**Radical terraces**

**Problem tree**

- Increased water pollution by sedimentation and silting
- Increased soil erosion and floods
- Limited adoption of radical terraces within rural communities
- Ignorance on radical terraces long-term benefits
- Lack of awareness on terraces long-term benefits
- Absence of adequate awareness raising mechanisms
- High cost of equipment/materials
- Insufficient local manufacturers (pick-axes, wheel barrow)
- Limited incentives
- Insufficient reference information
- Limited baseline surveys
- Limited land surveying initiatives

**Effects**
- Compromised income and food security
- Decrease in yields
- Increase in soil fertility loss

**Causes**
- Central barrier
Solution tree

- Reduced water pollution by sedimentation and silting
- Reduced soil erosion and floods

Radical terraces are well adopted within rural communities

- Education about radical terraces long term benefits
- Create awareness on radical terraces long term benefits
- Develop awareness raising mechanisms

- Reduction of equipment/materials cost
- Promotion of local manufacturers
- Provision of incentives

- Make available sufficient reference information
- Conduct baseline surveys
- Increase land surveying initiatives

Results
- Improved income and food security
- Increase in yields
- Improvement in soil fertility conservation

Main objective

Measures
Rainwater harvesting

Problem tree

- Increased vulnerability of the agriculture sector to the effects of CC
- Compromised income and food security
- Waste of water resources
- Increased soil erosion and floods
- Decrease in yields

Limited adoption of rainwater harvesting systems within rural communities

- Effects
  - Central barrier
  - Causes
    - Lack of skills and knowledge in Rainwater Harvesting
    - No specific training is provided on Rainwater Harvesting techniques
    - Absence of adequate technical training schemes
    - Difficult access to funds
    - Overall high interest rates (above 14%)
    - Absence of specific agriculture funding institutions
    - High cost of RWH systems
    - Use of expensive materials
    - Alternative low cost materials are not promoted
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

Solution tree

- Reduced vulnerability of the agriculture sector to the effects of cc
  - Water resources are saved

- Reduction in water pollution caused by sedimentation and silting
  - Controlled soil erosion and floods

- Improved income and food security
  - Increased yields

Rainwater harvesting systems are adopted within rural communities

- Provision of skills and know how in Rainwater Harvesting

- Provision of training on Rainwater Harvesting techniques

- Development of technical training schemes

- Make easy access to fund

- Overall low interest rates

- Reduce cost of RWH systems

- Use of cheap materials

- Establish specific agriculture funding institutions

- Promotion of alternative low cost materials

Results

Main objective

Measures
**Drip irrigation**

**Problem tree**

- Increased vulnerability to the effects of climate change
- Waste of water resources
- Possible water use related conflicts
- Increased competition between water uses
- Food security compromised
- Decrease in yields

**Limited acceptance of drip irrigation**

- Lack of technical skills on drip irrigation
- Difficult access to funds
- High interest rates (above 14%)
- High initial investment
- The technology is not given its right value
- Limited number of local retailers
- Low understanding of the vital role of water in plant growth and productivity
- Absence of adequate technical training schemes
- Limited agriculture funding schemes
- Absence of local manufacturers of drip irrigation equipment
- Ignorance
Solution tree

- Reduced vulnerability to the effects of CC
- Absence of water use related conflicts
- Improved income and food security
- Increased yields

- Saved water resources
- Reduced competition between water uses

- Increased acceptance of drip irrigation

- Provision of technical skills on drip irrigation
- Make easy access to funds
- Reduce initial investment
- Give the technology its right value

- Provision of specific training on irrigation techniques
- Reduce interest rates
- Promote local retailers
- Increase understanding of the vital role of water in plant growth and productivity

- Develop adequate technical training schemes
- Establish specialized agriculture funding institutions
- Promote local manufacturers of drip irrigation equipments
- Education
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

*Agro forestry*

**Problem tree**

- **Need of more inputs**
  - Water and soil nutrients losses
    - **Intensification of soil erosion**
      - **Limited adoption of agro forestry systems**
        - Limited awareness about Agro forestry long term benefits
          - Low awareness raising programs
        - Limited access to agro forestry inputs
          - Inadequate access to credit
            - Relatively high interest rates
        - Existence of technical knowledge gaps among agro extension agents
        - Lack of technical training on agro forestry systems
        - Limited capacity building programs
  - Food security compromised
    - Decrease in yields

---

*Barrier analysis and enabling framework report*
Technology Needs Assessment for Mitigation and Adaptation to Climate Change in Rwanda

Solution tree

Need of few inputs
  - Water and soil nutrients conserved

Improved income and food security
  - Increase in yields

Tangible reductions in soil erosion

Agro forestry systems are fully adopted

Improve awareness about agro forestry long term benefits
  - Increase awareness raising programs

Improve access to agro forestry inputs
  - Improve access to credit
    - Reduce interest rates

Improve technical knowledge among agro extension agents
  - Organize and conduct technical training on agro forestry systems
    - Improve existing and create new capacity building programs

Barrier analysis and enabling framework report 126
Annex 2- List of involved stakeholders and their contacts
